

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

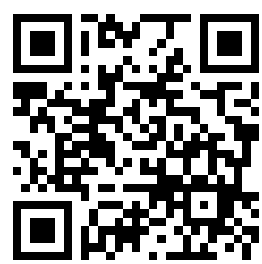
Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.

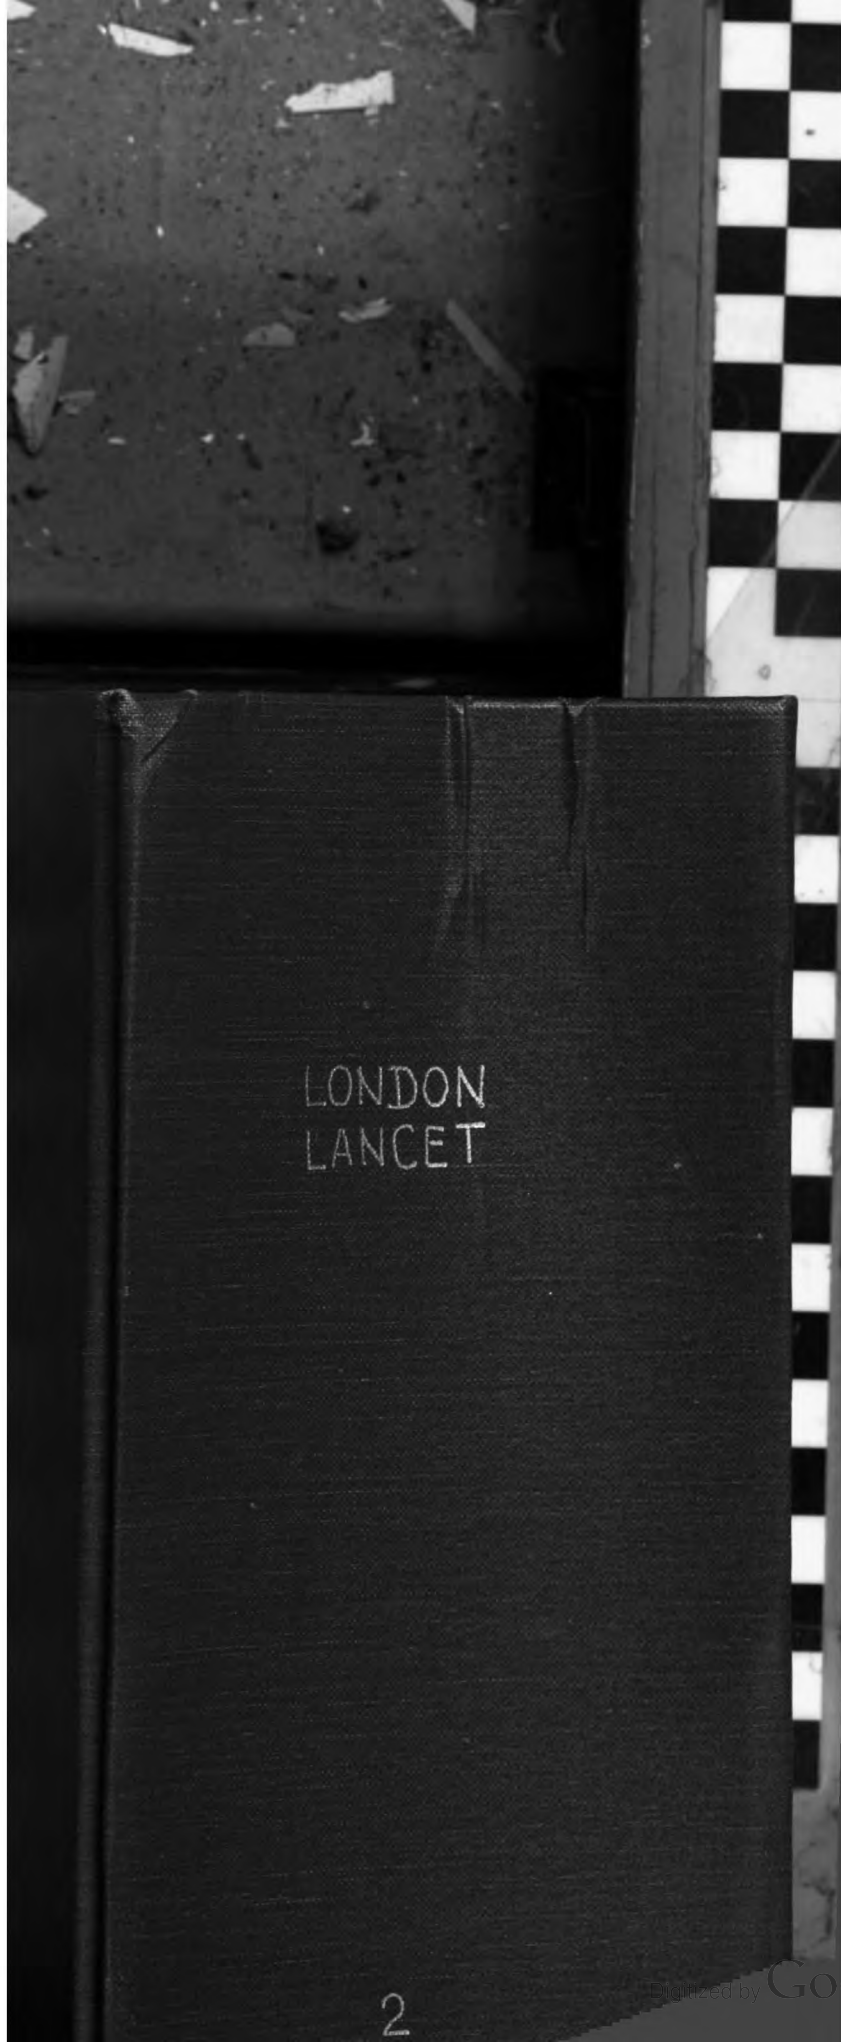
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.

+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.



Über Google Buchsuche



Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

ADDAMS HOSPITAL, MANCHESTER.—Two cases of rectal carcinoma; preliminary colotomy in one; excision; recovery (under the care of Mr. E. Stanmore Bishop), 849

BRADFORD INFIRMARY.—Perforating gastric ulcer; resection of the stomach; death after eleven days (under the care of Mr. W. H. Horrocks), 915

CHARING-CROSS HOSPITAL.—Two cases of typhoid fever, both complicated by hæmatemesis, and one by hæmorrhage; one recovery; one death (under the care of Dr. Green and Dr. Galloway), 1498

CHRISTCHURCH HOSPITAL, NEW ZEALAND.—Interesting surgical cases in the wards (under the care of Dr. Courtney Nedwill), 1574

CLAYTON HOSPITAL, WAKEFIELD.—A case of complete inversion of the uterus; recovery; remarks (under the care of Mr. W. Stanger), 207

ESSEX AND COLCHESTER GENERAL HOSPITAL.—Case of adenoma sebaceum (under the care of Mr. H. Laver), 674

GREAT NORTHERN CENTRAL HOSPITAL.—Case of S-shaped distortion of the septum nasi successfully treated by a series of operations and the use of retention apparatus (under the care of Mr. W. Spencer Watson), 93

GUY'S HOSPITAL.—Case of fracture of the os calcis; union of fragments in bad positions; resection of portion of os calcis; use of steel screw; recovery; remarks (under the care of Mr. W. Arbuthnot Lane), 463

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—Otorrhœa; lateral sinus thrombosis; operation; recovery (under the care of Mr. Bernard Pitts), 332—A case of radical treatment of umbilical hernia in a child; (under the care of Mr. Edmund Owen), 1224

KENSINGTON INFIRMARY.—A case of congenital absence of the rectum; necropsy (under the care of Mr. W. M. Woodhouse, senior assistant medical officer), 733

LIVERPOOL ROYAL INFIRMARY.—A case of perforated gastric ulcer; laparotomy; gastrostomy; recovery (under the care of Mr. F. T. Paul), 31—Case of hydrocephalus; trephining; opening of the fourth ventricle; recovery (under the care of Dr. Glynn and Mr. Thelwall Thomas), 1106

LONDON HOSPITAL.—A case of chronic inversion of the uterus cured by Aveling's repositor; remarks (under the care of Dr. G. E. Herman), 407—A case of double phlegmasia alba dolens in a young virgin, healthy except for slight anæmia (under the care of Dr. Herman), 848—Three cases illustrating the more severe complications of middle-ear disease; remarks (under the care of Mr. C. W. Mansell Moullin), 1290

MIDDLESEX HOSPITAL.—Two cases of induration of the erectile structures of the penis causing retention of urine (under the care of Mr. Henry Morris), 673—Two cases of inguinal hernia presenting unusual characters (under the care of Mr. Henry Morris), 979; acute perforation of an ulcer of the stomach; laparotomy; recovery (under the care of Dr. W. Pasteur and Mr. Henry Morris), 1573

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY.—Five cases of umbilical hernia (under the care of Mr. Frederick Page), 790

NORTH DEVON INFIRMARY, BARNSTAPLE.—A case of acute general exfoliative dermatitis (pityriasis rubra) (under the care of Mr. Walter Cooper), 207

NORTH-EASTERN FEVER HOSPITAL.—A case of scarlet fever; otorrhœa; thrombosis of the lateral sinus; pyæmia affecting right elbow and left hip; recovery (under the care of Dr. F. M. Turner), 1358

ROCHDALE INFIRMARY.—A case of hydrophobia (under the care of Mr. R. B. Sellers), 734

ROYAL BERKSHIRE HOSPITAL, READING.—Two cases of perforated gastric ulcer treated by operation; one recovery (under the care of Mr. Wm. J. Maurice), 980

ROYAL FREE HOSPITAL.—Chronic right-sided pleurisy with constriction of the superior vena cava simulating intra-thoracic tumour; remarks (under the care of Dr. H. Sainsbury), 1357

ROYAL SOUTH HANTS INFIRMARY.—History of a case of a tamarind stone in the right bronchus; necropsy; remarks (under the care of Dr. A. B. Wade), 1499

ST. BARTHOLOMEW'S HOSPITAL.—Two cases of fibro-angeioma of the naso-pharynx treated by operation; remarks (under the care of Mr. Anthony Bowlby), 913

ST. GEORGE'S HOSPITAL.—Two successful cases of laparotomy, one for diffuse septic peritonitis of four days' duration, and the other for ruptured hydatid cyst (under the care of Mr. A. Marmaduke Sheild), 789

ST. MARYLEBONE INFIRMARY.—A case of Graves' disease associated with idiopathic muscular atrophy; remarks (under the care of Dr. Lullum Wood Bathurst, late second assistant medical officer), 523

ST. MARY'S HOSPITAL.—A case of pleural and pericardial effusion following enteric fever and attended with the expectoration of a fibrinous cast of the bronchus; paracentesis of pleura and pericardium (under the care of Dr. Cheadle), 150

ST. THOMAS'S HOSPITAL.—The surgical report of a case of Jacksonian epilepsy with aphasia, intellectual impairment, and partial hemiplegia, treated by trephining (under the care of Mr. W. Anderson), 206—A case of injury to the ascending colon; formation of intra-peritoneal abscess; incision; fæcal fistula; recovery (under the care of Mr. G. H. Makins), 1042)—A case of tubercle of the bladder in a male; suprapubic cystotomy; recovery (under the care of Mr. W. H. Battle), 1165

SALOP INFIRMARY.—Notes of a series of cases of dilatation of the stomach treated by syphonage and other methods (under the care of Dr. Edward Cureton), 464

SEACOMBE COTTAGE HOSPITAL.—A case of ovariotomy, recovery, 1622

SIDCUP COTTAGE HOSPITAL.—Two complicated cases of inguinal hernia in women, treated by radical cure (under the care of Dr. G. W. Davis), 152

SWANSEA HOSPITAL.—A family history of herniæ (under the care of Mr. J. Kynaston Couch), 1043

TAUNTON AND SOMERSET HOSPITAL.—A case of tetanus treated with tetanus antitoxin; death on the fifteenth day after onset of symptoms (under the care of Mr. Samuel Farrant), 1432

VICTORIA HOSPITAL, BHOPAWAR AGENCY, CENTRAL INDIA.—Case of neuralgia of the kidney; nephrotomy; recovery (under the care of Surg.-Lieut.-Col. Duke), 407

VICTORIA HOSPITAL, HULL.—Cases of basal (subarachnoid) drainage; remarks (under the care of Mr. A. Parkin), 1166

WEST HERTS INFIRMARY.—Case of perforating gastric ulcer; laparotomy; death; necropsy (under the care of Dr. Russell Steele), 264

WEST LONDON HOSPITAL.—A case of traumatic tetanus treated by antitoxic serum; recovery (under the care of Dr. Aldren Turner and Mr. G. Lenthal Cheatle), 1431

WEST SUSSEX, EAST HANTS, AND CHICHESTER GENERAL INFIRMARY.—A case of pityriasis rubra (under the care of Mr. F. Skaife), 1107

WESTMINSTER HOSPITAL.—A case of unilateral tumour of the pons; death; necropsy (under the care of Dr. de Havilland Hall), 263—Secondary suture of the patella, with resection of the quadriceps extensor tendon (under the care of Mr. Walter G. Spencer), 1291

LIST OF ILLUSTRATIONS.

COLOURED.

Microscope Fields, illustrative of article on the Parasite of Malaria and Malarial Fevers (Dr. G. Thin), 12

Breathing Charts, illustrating the Croonian Lectures on A Contribution to the History of the Respiration of Man (Dr. W. Marcet), 6, 8, 9, 10

Enlarged Drawings of Maxillary Molar with Attached Growth, and of Portion of Right Maxilla and Photo-micrograph of a Section of Peridental Sarcoma, in illustration of article on Malignant Disease of the Peridental Membrane (Mr. A. H. Smith), 28

Glass Gastrostomy Tube fixed into Stomach to illustrate description of Operation for Perforated Gastric Ulcer (Mr. F. T. Paul), 31

The Benson-Lee Safety Lamp constructed with Carbon Burner, 36

Facsimile of part of a Letter written by the late Professor Huxley, including his Signature, to illustrate Obituary Notice, 65

Drawings of Hands and Fingers, to illustrate article on the Varieties of Rheumatoid Arthritis (Dr. R. F. Fox), 80, 81, 83

Sphygmographic tracings, to illustrate article entitled Some Considerations on the Chloroform Question, suggested by the Reports of the Hyderabad and THE LANCET Commissions (Dr. T. L. Brunton), 84, 85

Diagram illustrating article on the Disadvantages of Monocular Vision (Surg.-Maj. H. R. Whitehead), 89

Diagrams of Distortion of the Septum Nasi, and Drawing of Rectangular Dental Scaling Instrument, to illustrate description of a case of S-shaped Distortion of the Septum Nasi successfully treated by a series of Operations and the Use of Retentive Apparatus (Mr. W. S. Watson), 93, 94

An Aseptic Sponge-holder (Dr. R. W. Felkin), 100

A New Skin-grafting Knife (Mr. F. C. Wallis), 100

Drawing of Fœtal Malformation, showing Ectopy of the Liver, Omentum, and Bladder (Professor G. B. Todd), 140

Drawings of Maxillary Sarcoma, of Modification of Gunning's Splint, and of Plate worn in the Mouth, to illustrate article on the Mechanical Treatment after Partial Excision of the Lower Jaw (Mr. F. Newland-Pedley), 148, 149

The Thermo-Ether Inhaler (Dr. Carter), 158

Post-partum Uterine Compress (Mr. O. T. Slatter), 158

Photo-prints of Patient affected with Acute General Exfoliative Dermatitis (Mr. W. Cooper), 207

Improved Artery Forceps (Dr. E. M. Sympson), 214

Plans of New Buildings at the Middlesex Hospital, 225

Diagrams to illustrate description of a Modification of the Operation of Enteroplasty for Simple Stricture of the Intestine (Professor A. W. M. Robson), 259

Sections of the Brain, to illustrate description of case of Tubercle of the Left Optic Thalamus (Dr. A. J. Edwards), 264

A Shield for Protecting the Face during Applications to the Throat in Diphtheria (Dr. A. W. W. Dowding), 268

A Rare Condition of the Omentum (Mr. J. G. Smith), 331

A New Urœmeter (Mr. C. J. Mayhew), 334

Temperature Chart and Drawing of Upper Jaw-bone, to illustrate description of a Case of Chronic Glanders in a Horse-shoer (Dr. G. Sharp), 405

A New Adjustable Lock for Obstetric Forceps (Mr. E. M. Bourke), 411

Drawings of the Face and Head of M. Stambouloff, to show the wounds inflicted by his assassins, 421

Photo-print of Terra-cotta Donarium from Capua, 444

A Supernumerary Mamma in a Man (Mr. W. F. Adams), 462

The "Non-run-away" Bandage, 467

Drawings of Instruments and Operative Procedures, to illustrate Clinical Lecture on Diseases of the Eye (Dr. C. B. Taylor), 513-516

Diagrams in illustration of a New Bobbin for Intestinal Anastomosis (Mr. H. W. Allingham), 519, 520

Section of Spinal Cord from case of Spinal Softening limited to the parts supplied by the Posterior Arterial System of the Cord (Dr. R. T. Williamson), 521

A Modification of the Exploring Trocar (Mr. A. W. Prichard), 532

Portrait of the late Dr. J. S. Bristowe, 561

The "Zula" Syringe and Irrigator, 676

The "Arena" Vaporiser (Dr. W. H. Spencer), 738

An Invalid Cushion, 738

Drawing of Ruptured Pancreas, in illustration of article on Ruptures of the Pancreas, their Relation to Pancreatic Cysts, with some Remarks upon Treatment (Dr. R. F. C. Leith), 770

Drawing of Hands, in illustration of article on a Rare Form of Skin Disease following the External Application of Iodine Liniment (Dr. D. R. Doble), 778

A New Form of Pocket Case (Dr. S. H. Appleford), 853

A New Catch for Uterine and other Forceps (Dr. D. L. Roberts), 853

Drawing of Prehistoric Statuette, provided with a Truss, 869

Portrait of the late Louis Pasteur, 886

Microscope Field, showing Section of Atheromatous Cerebral Artery and numerous Physiological Diagrams and Tracings in illustration of Lecture on Atheroma and some of its Consequences (Dr. T. L. Brunton), 897-904

Diagram of Lines of Incision, illustrative of article on a Very Effectual Method of Treating Extensive Malignant Disease of the Breast (Mr. W. A. Lane), 905

Drawings of the Upper Surface of the Tongue, in illustration of article on Sore-throats in Influenza and the State of the Tongue as an Aid to Diagnosis (Mr. J. Terry), 906

Portrait of the late Surgeon-General Sir T. Longmore, 952

Sketch showing how much of the Tunica Vaginalis is removed for the Cure of Hydrocele, and Drawing of Outside Dressing used after Operations upon the Scrotum, in illustration of article on the Operation for the Radical Cure of Hydrocele by Excision of the Sac (Mr. C. B. Lockwood), 970, 971

Temperature Chart of case of Extra-Uterine Fœtation (Dr. M. Hand field-Jones), 973

Temperature Chart in illustration of article describing Three Successful Splenectomies (Mr. J. B. Sutton), 975

Diagram showing Hernial Sac open and Bowel behind Posterior Wall of Sac, illustrating description of two cases of Inguinal Hernia presenting unusual characters (Mr. H. Morris), 979

Drawings in illustration of paper on Spontaneous Disruption of Uric Acid Calculi (Dr. Plowright), 983

Portrait of the late Sir T. Crawford, 1013

Temperature Charts in illustration of article on Variations in the Temperature of the Mouth in Health produced by Local Application of Heat and Cold (Dr. W. S. Lazarus-Barlow), 1034, 1035

Temperature Chart from a case of Traumatic Tetanus treated with Tetanus Antitoxin (Professor N. I. C. Tirard), 1102

New and Improved Form of Hot-water Uterine Dilator (Dr. G. B. Todd), 1114

Charts showing Temperature and Incidence of Leucomaines and Urea in cases quoted in article on the Advantages of Oxidation (Dr. A. S. Eccles), 1151, 1152

Drawing of Median Cervical Fistula (Persistent Thyroid Duct) and Microscope Fields, showing its Histology (Mr. J. B. Sutton), 1161

Blood-pressure and Sphygmograph Tracings in illustration of the Bradshaw Lecture on some new Vaso-Dilators (Professor J. B. Bradbury), 1206-1212

An Improved Motor for Sewing-machines, 1236

A New Carrying Chair, 1236

Portrait of Inspector-General "James Barry," a Female Member of the Army Medical Staff, 1269

Sphygmographic and other Tracings in illustration of article on the Pharmacology of the Ipecacuanha Alkaloids (Dr. R. B. Wild), 1275, 1276

Portraits showing Hands and Face in a case of Mycosis Fungoides (Dr. L. Roberts), 1283

Paracentesis Needle for use with Hypodermic Syringe (Mr. W. H. Haggard), 1303

Carson's "Anti-stoop," 1303

Drawings of Calculi, in illustration of article on Urinary Calculi, their Formation and Structure (Sir G. M. Humphry), 1343-1346

Diagrammatic Outline of Narrow Couch and Patient in the Position for Removal of Adenoid Growths in the Pharynx (Sir W. B. Dalby), 1350

Photograph of Legs of case described in article on the Acute Inflammation of Bone and its Joint Complications (Mr. W. H. Battle), 1352

Diagram of Thoracic Viscera in case of Chronic Right-sided Pleurisy (Dr. H. Sainsbury), 1357

A New Tea Infuser, 1372

Temperature Chart of a Case of Tetanus treated with Tetanus Antitoxin and Chloral Hydrate (Dr. R. Hartley), 1425

Drawing illustrative of case of Cystic Tumour of Larynx (Dr. G. H. Mackenzie), 1426

Sections of Well, Privy, &c., in illustration of article on the Soil in its Relation to Health and Sanitation (Dr. G. V. Poore), 1486-1488

A Basin Enema Clip, 1511

Improved Clip for Ligaturing Vessels (Mr. A. H. Ward), 1511

Table, specially designed for Ophthalmic Operations, 1512

Diagrams in illustration of article on Electric Current from the Main (Dr. W. S. Hedley), 1571

A Portable Bamboo Operating Table (Mr. C. B. Keetley), 1588

Diagrams showing Means for Effecting Intestinal Anastomosis (Mr. P. J. Hayes), 1619

END OF THE SECOND VOLUME FOR 1895.

PRINTED and PUBLISHED by the REGISTERED PROPRIETORS at No. 423, Strand, and Nos. 1 and 2, Bedford-street, Strand, in the Parish St. Martin-in-the-Fields, Westminster, in the County of London.—Saturday, Dec. 28th, 1895.

The Cavendish Lecture
ON
DREAMY MENTAL STATES.

Delivered before the West London Medico-Chirurgical Society on June 20th, 1895,

BY SIR JAMES CRICHTON-BROWNE, M.D., LL.D., F.R.S.,
LORD CHANCELLOR'S VISITOR.

MR. PRESIDENT AND GENTLEMEN,—I have first to thank you for the honouring invitation conveyed by your council to deliver this Cavendish Lecture—an annual discourse established, I understand, to perpetuate the memory of the noble and benevolent peer by whom the West London Hospital was founded, but the title of which also recalls another scion of the same house — that great, silent, sagacious Henry Cavendish—who a hundred years ago helped to found that natural philosophy to which modern medicine owes so much, and one of whose experiments actually foreshadowed our most recent scientific triumph—I mean the discovery of argon. But while thanking you for your invitation I cannot but feel that there was perhaps some rashness in my acceptance of it, for, confined as I now am to the narrow precincts of officialism and without command of clinical material, I am scarcely entitled to follow in the footsteps of those who have hitherto addressed you from this chair, who have always had practical aims in view, and have communicated to you the fruits of their own experience in such a manner as to be immediately serviceable in your professional work. But medicine is many-sided and touches, or is touched by, almost all human affairs, and it occurred to me that I might not unprofitably conduct you this evening into a bypath of pathology, and ask you to leave the bedside for a little and consider with me certain mental conditions that are encountered in daily life that have a literary and philosophical interest, and that are not, I believe, without great medical significance. I have therefore culled from the faded leaves of an old notebook some observations on curious, fleeting, but elaborate psychical modifications, which have been designated "dreamy mental states," also "voluminous mental states," likewise "intellectual aurae," and which have not yet received in this country the amount of attention they deserve. Now, the simplest form of these dreamy mental states—a sense of reminiscence it has been called by some, a sense of prescience by others, and the application to it of such apparently contradictory names suggests that it is somewhat mysterious in nature and difficult of interpretation—is to be found described vaguely, but recognisably, in the works of many of our most gifted writers. It consists in an impression suddenly taking possession of the mind that the passing moment of life has been once lived before or must be once lived again—that surrounding objects have been seen once before exactly in the relations in which they at the instant present themselves. "How often," says Sir Walter Scott in "Guy Mannering"—"how often do we find ourselves in society which we have never before met, and yet feel impressed with a mysterious, ill-defined consciousness that neither the scene nor the subject is entirely new; nay, we feel as if we could anticipate that part of the conversation that has not yet taken place." "We have all some experience," says Charles Dickens in "David Copperfield," "of a feeling which comes over us occasionally of what we are saying or doing having been done in a remote time, of our having been surrounded dim ages ago by the same faces, objects, and circumstances—of our knowing perfectly well what will be said next, as if we suddenly remembered it." Rossetti says in "Sudden Light":

> "I have been here before,
> But when or how I cannot tell:
> I know the grass beyond the door,
> The keen, sweet smell,
> The sighing sound, the lights around the shore.
>
> "You have been mine before—
> How long ago I may not know:
> But just when at that swallow's soar
> Your neck turned so,
> Some veil did fall—I know it all of yore."

Edward Dowden says:

> "There is a murmur in my heart I hear,
> Faint, oh! so faint, some air I used to sing,
> It stirs my sense, and odours dim and dear
> The meadow breezes bring.
>
> "Just this way did the quiet twilight fade
> Over the fields and happy homes of men,
> While one bird sang as now, piercing the shade,
> Long since, I know not when."

Without multiplying illustrations of this simple, dreamy mental state as experienced by masters of the literary craft, I would point out that almost invariably when these masters have attempted to explain it or have speculated as to its origin, they have regarded it as a vestige of a previous state of existence, as an echo from a life anterior to the present one. The thought that is of the essence of the state is transient and vanishes before it can be grasped; it is often connected with circumstances of the most commonplace or trivial description—Oliver Wendell Holmes says it used to occur to a poor student when he was blacking his boots—and yet it startles as if it were a flash of revelation, and leaves behind it a sense of solemnity and doubt. Those who are visited by it know well that it is no ordinary reminiscence, no error of memory, no mere poetical fancy, but an absolute identification of the present with the past; and it is little wonder that they should translate the perplexity which accompanies it into ghostly glamour and trace it back to prehistoric times.

> "Our birth is but a sleep and a forgetting:
> The soul that rises with us, our life's star,
> Hath had elsewhere its setting,
> And cometh from afar;
> Not in entire forgetfulness,
> And not in utter nakedness,
> But trailing clouds of glory do we come
> From God Who is our home."

Thus Wordsworth wrote, and it is to the cloudy remnants, which may, according to him, be detected in infancy, that dreamy states in adults have been most commonly referred. Coleridge, who was very subject to dreamy states of all sorts and sizes, seems to have been disposed to take this view of their hidden meaning, for he said:

> "Oft o'er my brain does that strange fancy roll,
> Which makes the present, while the flash doth last,
> Seem a mere semblance of some unknown past
> Mixed with such feelings as perplex the soul
> Self-questioned in its sleep; and some have said
> We lived ere yet this robe of flesh we wore."

And Russell Lowell was evidently of the same way of thinking, for he said:

> "And now sometimes we seem to find,
> In a dark crevice of the mind,
> Some relic which, long pondered o'er
> Hints faintly at a life before."

Coventry Patmore, too, dealing with the same topic, arrives at the same conclusion, set forth in these words:

> "At times some link of harmony seems missing, and we anon
> Remember states long ended ere we left the womb,
> And see an awful something flashing to us from the tomb,
> The zodiac light of new states dashed tremendously with gloom,
> We tremble for an instant, and a single instant more
> Brings absolute oblivion, and we push on as before."

It is not at all improbable that the doctrine of human pre-existence owed its origin to unaccountable reminiscences of the kind alluded to in the passages quoted. To imaginative minds in superstitious ages they may have seemed to afford glimpses of real insight into an otherwise impenetrable past, and even to matter-of-fact minds at the present day it must be admitted they sometimes bring with them convictions of metempsychosis which it is difficult to shake off. But with the transcendental aspects of these reminiscences or dreamy mental states we are not here concerned. It is ours to deal with them from a purely medical point of view, and so we must regard them, not as intimations of immortality, but as revivals of hereditarily transmitted or acquired states in new and special combinations.

Dreamy states, as I have already remarked, have been experienced and recorded by many of our most eminent writers, and as regards their general prevalence it has been assumed that they are a universal human experience. Dickens says we have all had them, and the usual introduction to any description of them is that they are a feeling with which everybody is familiar. "Everybody is familiar," says Thomas Hardy in "A Pair of Blue Eyes," "with those strange sensations we sometimes have that our life for the moment exists in duplicate, that we have lived through that moment before

Digitized by Google

or shall again." No doubt these dreamy states are very common amongst us at the present day, but it will, I am sure, be found on inquiry that they are by no means all-embracing, and that while they abound amongst the educated, the refined, and the neurotic classes, they are comparatively rare amongst the unlettered, the prosaic, and the stolid masses of our people. The difficulty of getting information about them is considerable, for those who have experienced them generally manifest a disinclination to talk about them, from a not unwarrantable suspicion that they are somehow morbid in their nature; and those who have not experienced them cannot comprehend what is meant by them, and often treat questions bearing on them with a levity like that of the young American, who, when interrogated respecting them, replied that he never lighted a cigar without the deepest conviction that he had done the very same thing not once, but many times before. Still, a little careful investigation as to their distribution will, I am satisfied, conduct to the conclusion that dreamy mental states, although widespread, are by no means universal and cannot with propriety be called normal phenomena. The fact is that they emerge only at a certain state of mental evolution, rarely occurring in a child under eight years of age or in a man or woman of less than average mental development, and are not themselves a part of the evolutionary process, but one of the accidents by which it is attended. They do not present themselves before that stage of intellectual growth at which the capability of entertaining abstract ideas is attained, and they find no place in a scheme of natural and organic mental expansion, but are an interference with the chiaroscuro of perfect mental health, and the first step in a series of changes which, extending through many degrees of mental dissolution, ends in complete coma or obliteration of mind. I shall hope to show that these dreamy states, so far from being normal even in their slightest and simplest form and occurring in presumably healthy persons, involve disorder of mind, trifling and transitory no doubt, like cramp in a few fibres of a muscle, but disorder nevertheless dependent on a defect of consciousness in one direction, indicated by vagueness as to present surroundings, and an increase of consciousness in another direction, indicated by the too vivid revival of former surroundings. There is in them a negative element in the loss of control of the highest centres and a positive element in the raised activity of other nervous arrangements, permitting of new cerebral combinations somewhat akin to those which take place during the activity of the imagination and flights of genius. If the sense of beauty is vision raised to a higher power, a dreamy mental state is memory diving to a lower than its accustomed level and bringing to the surface deeply submerged personal annals, or even still more unfathomable ancestral traits. A dreamy state it may be conveniently called, and dreamy in some aspects it undoubtedly is, and yet, strictly speaking, it is not comparable to a dream, for it involves a residuum of object consciousness larger than a dream contains and a volume of subject consciousness to which a dream rarely reaches. It has peculiar features of its own and stands in the same relation to a dream that the darkness of an eclipse does to the more frequently recurring darkness of night.

I have hitherto spoken of dreamy mental states of the most ordinary and uncomplicated type—those that are least removed from normality and consist in reminiscence: but it must be pointed out that such states are of many different kinds and that those that commence in reminiscence sometimes branch out into more elaborate manifestations. They have not yet been classified, and this is to be regretted, for the accurate observation and arrangement of them would in all likelihood throw much light on their nature and almost certainly reveal that, notwithstanding their diversities, they often closely resemble each other as occurring in different individuals, and fall into several groups corresponding probably with disorder of several different cerebral areas. As yet, however, all we can do is to enumerate some of their characteristics and varieties. The most general description of them is that they are indescribable and transcend all common experience, and the crudest analysis discloses this much—that they consist in an exaltation of subject consciousness and a degradation of the power of attention for the time being, and are almost invariably concerned, however vaguely, with those ultimate scientific ideas—space, time, matter, motion, force, and the like—which are beyond the domain of certain knowledge, and, according to Herbert Spencer, unthinkable. Contrary to all experience, they have yet apparently the highest experiential validity. They declare themselves now as tamperings with those intuitions that yield the consciousness of continued existence, and again as excursions into that infinite field that lies behind appearances and of which it is dangerous to affirm or deny anything. Plunges they are into these depths of outer mystery in which the certitudes of science lose themselves and out of which, it has been said, the certitudes of faith arise. Momentary realisations they become of Nirvana or the cessation of being, or foretastes of purgatorial pains more searching than any that Dante conceived. "Dream not, Coleridge," Charles Lamb wrote, "of having tasted the grandeur and wildness of fancy till you have gone mad." "Think not, Lamb," Coleridge might have replied, "of having touched the skirts of immensity and mystery until you have had a dreamy mental state." The victims of dreamy mental states, striving to convey some notion of them, tell us that they consist in a feeling of being somewhere else—in double consciousness—in a loss of personal identity—in a going back to childhood—in the vivid return of an old dream—in losing touch of the world—in a deprivation of corporeal substance—in a loss of a sense of proportion—in momentary black despair—in being at the Day of Judgment; and they supplement whatever phrases they use with the assurance that it is impossible to put into words such strange and incomprehensible visitations.

That dreamy mental states, even of the most familiar type—those, I mean, which consist in reading into the present some version of the past—are abnormal in their essence and morbid in their tendencies may, I think, be demonstrated by a study of their transitions, their associations, their congeneric conditions, and their consequences. As represented to us in literature, these simple dreamy states are occasionally linked with other mental states akin to them, but of a more pronounced pathological character. In Tennyson's writings, for example, we have several references, that are not all obscure, to what may be termed the ordinary dreamy mental state. In "The Two Voices" he sings:

> "Moreover, something is or seems,
> That touches me with mystic gleams,
> Like glimpses of forgotten dreams—
>
> "Of something felt, like something here;
> Of something done, I know not where;
> Such as no language may declare."

And in the "Early Sonnets" he thus delivers himself:

> "As when with downcast eyes we muse and brood,
> And ebb into a former life, or seem
> To lapse far back in some confused dream
> To states of mystical similitude;
> If one but speaks or hems or stirs his chair,
> Ever the wonder waxeth more and more,
> So that we say, 'All this hath been before,
> All this has been I know not when or where.'"

But in Tennyson's writings we have also references to other mental states which have about them quite as convincing a ring of personal knowledge, and the morbidity of which cannot be questioned. Thus in "The Princess" we are told that the hero, who belonged to a race haunted by a hereditary nervous affection, was himself afflicted by—

> "Weird seizures, Heaven knows what:
> On a sudden in the midst of men and day,
> And while I walked and talked as heretofore,
> I seemed to move among a world of ghosts,
> And feel myself the shadow of a dream."

In these words it is not difficult to recognise an outline of *petit mal*, and Tennyson himself names these seizures epilepsy, and we have, therefore, in his poetical biography appreciations of a simple dreamy mental state and of the epileptic state, of which these dreamy mental states are so often the prelude or accompaniment. In Tennyson's poems these two states are not brought into immediate relation, but in our professional experience it is no uncommon thing to find the one state signalising the onset of the other or alternating with it; and it is no uncommon thing for us to observe that with or without some subjective sensational warning of an approaching epileptic fit there arises a dreamy mental state, which in that connexion has been designated an intellectual aura. It is not suggested that the dreamy mental state under such circumstances is directly due to the epileptic discharge, but there are grounds for holding that it depends on the heightened activity and increased energising of nervous arrangements intimately linked with those in which the true epileptic discharge begins. A truly epileptic or sudden and excessive discharge of the highest nervous arrangements results, not in ideas however vague, but in the negation of thought or loss of consciousness, and ideas properly so

Digitized by Google

called attend the excitation and not the explosive discharge of these arrangements. Intellectual aurae or dreamy mental states are, therefore, precursors and not integral parts of epileptic fits. A medical man who, five-and-twenty years ago, contributed to the *Practitioner* an interesting memoir of his own case, said that he had suffered from boyhood from dreamy mental states of reminiscence, or a startling conviction that he had once before been placed in the exact circumstances in which he found himself, and that immediately before his first epileptic fit, which occurred in middle life, these dreamy states recurred with unusual frequency and intensity. "Since my first attack," he went on, "I have only had few recurrences of the feeling, but on two occasions these were followed the next day by an epileptic seizure." One patient of Dr. Hughlings Jackson reported that his fits began by "a sort of referring to old things that have happened," after which he lost himself; another intimated that old scenes reverted for hours before a fit; another said, "If I were walking along and had a fit I should think, 'Oh! I saw that before'"; and a patient of my own, before each fit—and his fits were marked by violent convulsions and tongue-biting—had a similar impression accompanied by intense terror and alarm. Dr. Joseph Coats of Glasgow has narrated the case of an intelligent man who stated that with few exceptions his fits had been preceded by giddiness and "a peculiar "thought," as he expressed it. He attached great importance to this 'thought," saying that if it were known his whole case would be explained, and although he could not tell what the thought was he was confident that it was always the same. He always recognised it when it occurred, and tried to fix it in his memory, but he invariably forgot it when the fit was over. Now this case recorded by Dr. Coats, and another case in which "a dreadful queer feeling" gave notice of fits when they first commenced, but was gradually lost as they became confirmed and severe, suggest that dreamy mental states perhaps prelude epileptic fits more frequently than the testimony of those who suffer from such fits would lead us to suppose, for it is undoubtedly true that when consciousness is suddenly interrupted there is often obliteration of the records of conscious experience for a period, longer or shorter, before the exact moment at which the interruption occurred. The impressions received, the ideas developed on the sensitive plate of the brain, can only apparently be fixed there so as to be capable of reproduction while conscious activity is maintained, and an abrupt cessation of brain function not only arrests sensation and perception, but prevents the due registration of some sensations and perceptions that have taken place immediately prior to the break in the chain of conscious life. The blackness of insensibility casts a dark shadow behind it. In cases of concussion or injury of the brain inducing coma we frequently find that there is after recovery a mental blank as to incidents that occurred some time before the accident, and in cases of epileptic seizure it may sometimes be demonstrated that events occurring a few minutes before the actual invasion of the fit or of any premonitory symptom of it, at a time when the intellect was clear and conduct rational, cannot by any effort be recalled after the fit is over. It may well be, therefore, that mental experiences in juxtaposition to the fit—and constituting, indeed, its initial symptom or warning—are irrecoverable in memory, and so the assurances of persons subject to dreamy states and epileptic fits, that the former do not usher in the latter, cannot be received as trustworthy. The late Professor Laycock of Edinburgh recorded a case of epilepsy in which the paroxysms were inaugurated by a peculiar cry, a cry which, however, came sometimes independently as a false alarm, not being followed by unconsciousness or convulsions, and whenever that cry came alone the man was aware of it and discussed it afterwards, wondering what it meant; but when it was followed by a fit he had no after knowledge of it, and denied its having been emitted; no permanent record of it had been made. And just as with that cry, dreamy states, dread thoughts, or emotions of terror, which when standing alone can be remembered, may be, when linked with a fit irretrievably blotted out. The frequency with which a cry begins an epileptic fit might perhaps be regarded as some indication of the frequency of dreamy states at that juncture, for the cry is mostly strongly suggestive of acute mental trouble, and is probably, in some cases at any rate, determined by a feeling of fear present at the moment, but not subsequently recollected, and it is not to be lost sight of, in this connexion, that a sudden fright is believed to be one of the most common exciting causes of epilepsy.

But whatever may be the frequency of dreamy mental states as psychical aurae in epilepsy, I feel satisfied that the risks attending them in connexion with epilepsy may be measured by the degree in which an emotional element enters into them or in which they tend to pass over into action. Those states that are colourless or agreeable are comparatively innocent, whereas those that are attended by fear, pangs, anguish, horror, or visceral disturbances are peculiarly apt to lead up to convulsions. Many cases have been noted—I shall shortly refer to some of them—in which dreamy mental states mingled with fear have ultimately merged in epilepsy, and this danger seems to me to be peculiarly great when the fear is connected with visceral sensations, such as difficulty of breathing, oppression of the chest, palpitation of the heart, or a feeling of sinking at the epigastrium. A girl who was under my care in the West Riding Asylum, and who had suffered for years from what she called "a frightened belly-ache" and could only further explain as a feeling of fear at the pit of her stomach, after a time became epileptic, her fits being always immediately preceded by the "frightened belly-ache," which lasted for about five seconds, and allowed her time to give notice of the impending seizure, which she invariably did by piteously shouting out, "Bump my back." If before the actual appearance of convulsive spasms anyone could reach her and obey her mandate by giving her four or five smart blows over the lower dorsal vertebrae the fit was very frequently averted. Another girl under treatment at the same time, who before becoming epileptic had been subject to slight fainting feelings accompanied by the dread of being killed, gave notice of her attacks by crying out, the instant before she dropped, the words "Dangers and bolsters!" which were understood to convey an announcement of the revival of her old apprehension and the expression of a wish that a pillow might be brought on which to rest her head. Still another girl, who was epileptic, alleged that for several years before her fits came on she had had occasionally an indescribable feeling of "awful disgust"—a feeling that had once or twice ended in vomiting, and that had often recurred when a fit was impending.

In many cases of epilepsy that have been associated with dreamy mental states the infusion in these states of a feeling of fear and of obscure visceral sensations may, I believe, be made out, visceral sensations in this connexion being more frequent than crude sensations of coloured vision, or noises in the ears, or more elaborate sensations of spectral faces or hearing voices.

But not less ominous than visceral sensations in connexion with dreamy states are actions which are repeated whenever these states recur, for these indicate a deepening or diffusion of the cerebral disturbance which makes it correspond with somnambulism rather than with dreaming. Running movements may only betoken the dominant emotion of fear; masticatory movements, smacking of the lips, and spitting, which Dr. Hughlings Jackson has observed, may mean a crude sensation of taste; but spasmodic movements are premonitory of convulsions. In one case of dreamy mental states which ended in epilepsy there were during these states rapid clutching movements of the hands. In dreamy mental states that are to prove harmless there is mostly tranquillity, but where muscular agitation accompanies them they are not unlikely to advance into something worse than themselves.

I have endeavoured to indicate the morbid character and tendencies of dreamy mental states by illustrating their transition into epileptic seizures or interspersal amongst them; but this is not the only pathological transformation that they undergo, for a history of them is not rarely discoverable in those who have become insane without the intervention of epilepsy, and the passage from them into states of mental disease may occasionally be traced out. St. Pierre, the author of the ever-fascinating "Paul and Virginia," when overcome by disappointment and humiliation and tottering on the brink of madness, was harassed by seizures which had certainly much in common with dreamy mental states. "I was struck," he says, "with an extraordinary malady; streams of fire like lightning flashed before my eyes; every object appeared to me double or in motion. In the finest day of summer I could not cross the Seine in a boat without experiencing intolerable anxiety. If in a public garden I merely passed a piece of water I suffered from spasms and a sudden feeling of horror." A patient of my own, who had a sharp attack of mania with delusions of suspicion and suicidal impulses for two years before its development, suffered from dreamy mental

Digitized by Google

states. These first took the form of a sudden dead feeling in the head, said to be both psychical and somatic, which came on almost every day; but after three months they assumed a new shape, a sudden sense of fear, during which all objects around him seemed to grow distant and afterwhich there was violent palpitation of the heart. Still a third transformation took place, when the sense of fear changed into a wild desire to run round in a circle and scream, and after that came mania. The whole insanity of a patient of mine seemed to consist in an endless chain of dreamy mental states of a claustrophobic nature. She was of good memory, intelligent, and rational, but whenever awake was distressed by constantly recurring painful impressions or obsessions, which she described as a feeling of "entombment." Every few minutes she felt as if she was in a house in the middle of a great wood and could never get out of it, knowing all the time quite well where she really was. Whenever she looked at the door of the room in which she was sitting she had a horrible feeling that it was too small and that she could never get through it.

But not more by their transitions than by their associations is the true character of dreamy mental states betrayed, for almost invariably they occur during impaired bodily health or in states of exhaustion, or have bound up with them, either in the sufferer himself or in the family to which he belongs, other and unmistakable symptoms of nervous disease. They rarely stand alone, but have for the most part side by side with them other sure signs of a want of equilibrium or of degeneration in the nerve centres. Dr. Hughlings Jackson has reported a case in which dreamy mental states consisting in the impression of having fallen down a coalpit were associated with epileptic seizures and left hemiplegia, due to a coarse lesion of the right hemisphere; and it is noteworthy that of the distinguished men of letters whose confessions of dreamy mental states have been quoted Scott, Dickens, and Rossetti died of brain disease. One of the most striking and persistent cases of dreamy mental state that I have ever met with was that of a man whose father was epileptic, who had one brother a dipsomaniac, another a confirmed opium-eater, another an epileptic, another a lunatic, and one brother and several sisters free from nervous taint. I cannot, perhaps, better convey to you some notion of the associations of dreamy mental states, personal and hereditary, than by recounting the history of a family in which, by a lucky chance, I have been able to trace them through four generations.

A lady who lived at the close of the last century and up to the middle of the present one was subject from girlhood to what were then called "spells of absent-mindedness," but which, seen now, by the light reflected on them by the experiences of her descendants, may be safely pronounced to have been dreamy mental states. This lady was always nervous and peculiar, and is reported at one period of her life to have displayed insane jealousy; but she bore a family of ten children to a healthy and vigorous husband and died at an advanced age from epilepsy, from which she had suffered for some years, the fits being heralded by an aura of the left hand and arm, and being sometimes prevented by the firm ligature of that limb. It was not possible to ascertain the pathological histories of her ten children beyond this—that one boy died from convulsions in infancy, and one daughter from phthisis at adolescence, and that two of them, a boy and a girl, manifested neurotic derangements clearly derived from her. One son was distressed in youth and manhood by brief seizures which may be described now as loss of orientation, but which he himself nicknamed "a topographical topsy-turvy." Generally when out walking and alone his consciousness of his geographical bearings became confused, and this without vertigo or apparent movement of objects to one side. In an instant the world seemed to him to have whirled round, and he could not for the life of him make out the points of the compass, although the landscape and all objects around him remained unchanged in appearance. He felt that it was a matter of pressing moment that he should recover his true position in space, and for a few seconds was in a tremor of perplexity and dread, and then all at once everything was righted and he knew where he stood and said to himself with delight, "That is the north, and I know now exactly how the south and east and west lie." The seizures or bewilderments continued to annoy him, but at widening intervals, until he was about forty years of age, when one day, while standing on the edge of a rock and looking at a waterfall in the Scottish Highlands, he fell suddenly in a violent epileptic fit, and was only saved from death by the presence of mind of a companion. From that date he never again experienced loss of orientation, but he had from time to time epileptic fits, chiefly nocturnal, which did not, however, impair his intellect or health, for he died at a ripe age from Bright's disease. His sister, a woman of great intelligence and energy, was subject from girlhood up till middle age to periodical attacks of migraine with fortification outlines and vomiting, which may be regarded as an allotropic form of a dreamy mental state or a sensory epilepsy. She married and had eight children, one of whom died from acute hydrocephalus and two from typhoid fever. Of the five survivors two, a son and a daughter, became the victims of dreamy mental states at about ten and nine years of age respectively, and continued to suffer from them with gradually diminishing intensity and frequency up till middle life. In these two cases the dreamy mental states were identical in nature, and although the sufferers had never compared notes about them, being somewhat ashamed of them, were described in precisely the same terms to the physician who ultimately made inquiries about them. They were called "frightened feelings" and consisted in a loss of personal identity The youth, who gave the fullest account of them, said that suddenly he lost his hold of the universe and ceased to know who he was. Everything seemed changed in a twinkling, and he lost his relations to time and space. He felt intense terror while the attack lasted lest he should never become himself again, and after it was over there was always violent palpitation of the heart. He was never unconscious during the attack, which lasted ten or twelve seconds at the most, for he could pass from one room to another or run upstairs and voluntarily call out certain names while it lasted. He generally called out repeatedly and in a hurried manner his own name or that of a sister who was about his own age, and he affirmed that the calling out of these names helped him to recover his identity. The frightened feelings almost invariably came on when he was alone, and when assailed by them he ran to seek society, as the presence of anyone drove them away. They never came on when he was engaged in conversation or in work, mental or bodily, involving effort, but always when he was ruminating or carrying on some routine employment. At one time he could bring them on by gazing intently at his own face in a looking-glass, or by allowing himself to drift into a particular train of thought or becoming "abstract and metaphysical," as he termed it. If he asked himself, "Who am I?" "What am I?" "Where do I come from?" "How do I stand related to persons and things around me?" he inevitably had an attack, and the very fear that he might drift into this current of speculation often irresistibly drove him into it, and ended in a repetition of his sufferings. Fear of any other kind, however, or emotional excitement never induced an attack; but he distinctly recalled that after being taken to the Whispering Gallery of St. Paul's, and being terrified by looking down from its height into the cathedral below, he had several times an attack when the terrific impression he then received recurred to him in memory and created a sense of his own insignificance. The attacks never occurred in the morning, only occasionally in the afternoon or early evening, and by far most frequently as he was undressing to go to bed. As they wore off in adult life the last vestiges of them were experienced while he was drowsy and just falling to sleep. Suddenly he would spring up in bed, conscious that his old terror was upon him again, though in a dim and distant way, and always after he did so there was palpitation of the heart. He led an active life, but his health and mental condition were, he himself thought, appreciably affected by his attacks, for he never fulfilled the intellectual promise of his boyhood, but was impulsive and irritable and suffered much from depression and general debility, and finally from angina pectoris. His sister, whose attacks were in all respects similar to his in character and consisted in a temporary loss of personal identity, with a feeling of infinite distress, embarrassed breathing, and palpitation, but less severe and frequent, was also of a highly nervous temperament and had an attack of mental depression with rupophobia. The brother married and had two children, a boy and a girl, both of whom suffered from dreamy mental states, and whose cases I was able to observe. The boy began at the age of ten, when fragile and delicate, to have odd and horrid feelings. They generally came on when he was in bed, but they have happened in church, and at a time when he was not

Digitized by Google

apprehending them. Except in church he never had them in the presence of anyone, but always when alone. He could not explain the attacks further than by saying that he felt as if he were "just nothing" while they lasted, and was terribly frightened, his heart beating very fast. During the continuance of the attacks, which never exceeded a few seconds, it was usual for him to touch or pinch his body and limbs with his fingers and thumb and say to himself, "Who am I?" "Am I alive?" It was for the most part while he was thinking deeply on "religious or out-of-the-way subjects," as he phrased it, that the attacks came on, and occasionally he was able, on feeling one approach, by thinking to himself, "Oh, it is all nonsense, I am in a room, that is a chair and this a bed," to ward it off; thus by a strong effort recovering his object consciousness when it began to fail. While suffering from these attacks he was disturbed by violent muscular jerks as he was dropping off to sleep, and on one occasion had a numb feeling followed by shaking down the left arm. He cried out for help and was found sitting up in bed and holding his left arm, which was trembling. At the same time he had a strange dream which recurred again and again, and with which he became painfully familiar. In the beginning of the dream he felt enormously large in all dimensions, as if he were the length of the room, and swollen out so that if he moved his leg it felt like the leg of a giant. Then there came a vast haze, and vacancy and great fear, and in the haze black sticks or stripes appeared all round and seemed to be closing in upon him, and then in terror he awoke. Under the impression that they were just "silliness," and that he would be laughed at if he spoke of them, this boy concealed his dreamy states until he was nearly fourteen years of age, when they became so severe and distressing as to make his life miserable, and he was obliged to acknowledge them. He was sent to the country, freed from brain work, carefully scrubbed, and put upon bromides, and the attacks rapidly diminished in number and severity, but up till his twentieth year he continued to suffer from them from time to time.

This boy's sister at eight years of age began to suffer from attacks similar to his, which she also for a time kept to herself because she thought they were due to "conscience," but which were brought to light when his were revealed. They came on, she said, never when there was bustle around or when anyone was talking to her, but always when she was alone, especially when she was sitting doing nothing, looking at her dress or at the floor, and she could induce them when alone by gazing at her hands, saying to herself it was funny that she was alive, and wondering how it was that she came into the world. "The lost or funny feelings" in her, for thus she labeled them, did not cause terror, but only uneasiness, and made her feel like "a nonentity," and were not followed by any disturbance of the heart's action. They lasted only for a few seconds. Once or twice she had numbness of the left hand and transient lateral hemianopia. Like her brother, she had startings on going to sleep and constantly recurring dreams, in her case of skimmings over the surface of the ground and flying downstairs. Objects at which she gazed intently sometimes grew smaller and smaller and receded into distance, and this experience was always followed by a feeling of sleepiness for a few minutes. When just falling asleep she would often hear a low murmuring, crooning noise, as if someone were sneering at her—a sound which was horrid and created alarm, and was so real that she was obliged to jump up in bed and rub her ears. At other times when falling asleep she would have a loud dinging in her ears, and while still awake, but lying with closed eyes, she often saw long black figures which changed into little dumpy white ones. On one occasion she saw a spectral face, and having raised herself in bed watched it grinning at her in a corner of the room and noted that it had very white teeth and red hair. She also was put under treatment as soon as her dreamy states were discovered, and improved rapidly when relieved from educational pressure and carefully nourished. As the dreamy states diminished in number she became visibly happier and more animated, but she continued to suffer from them once or twice a month until she was eighteen years old, when after an attack of chlorosis they again became very troublesome. In another year, however, they again yielded to treatment, and now she is, she reports, altogether free from them.

I am afraid I have wearied you by this tedious story of the dreamy mental states of a family. It is, however, I believe, unique in affording conclusive evidence of the hereditary transmission of these states through four generations, and it is assuredly instructive as regards their affinities. I cannot now touch upon the many points of interest which this story presents, and even what may have seemed irrelevant details in it have an interest of their own. But I should like to direct your attention to one or two of its more suggestive features.

In the first place then I would ask you to note that it illustrates to us not merely the transmission of dreamy mental states, but of a particular dreamy mental state, and that one of a very elaborate description. The account given of the dreamy mental state in the first generation is too indefinite to enable us to decide its real nature, and in the second generation that state had reference to ideas of space; but in the third and fourth generations, and in four different individuals, it consisted in a loss of personal identity. We have thus a particular aberration of mind springing up spontaneously and independently in four persons, that aberration being exactly the one which the dreamy mental state assumed in the late Lord Beaconsfield, who wrote: "I was not always assured of my identity or even existence, for I sometimes found it necessary to shout aloud to be sure that I lived, and I was in the habit very often at night of taking down a volume and looking into it for my name to be convinced that I had not been dreaming of myself."

In the second place I would ask you to note in the story rehearsed the relations of dreamy mental states to evolutionary changes in the brain. The age at which these dreamy states first occurred is recorded in four cases; it was ten in the cases of two boys and eight and nine in the cases of two girls, and it is to be remembered that at that period of life cerebral development in the female is from one to two years ahead of that in the male sex. In these four cases, too, the dreamy states persisted only while cerebral and mental development was going on actively and vanished when maturity was attained.

In the third place I would ask you to note in this story that in four cases the dreamy states came on almost invariably in solitude, which is favourable to subjective contemplation, and that in three cases they were particularly prone to show themselves, like the hallucinations of chorea, during the invasions of sleep, when the brain is freed to a large degree from external solicitations and volitional control, and is in a transitional state.

In the fourth place I would ask you to note in this story that in three cases—all right-handed persons—indications were given by modifications of sensation and movement in the left arm that along with dreamy states there was, or had been, damage or disorder of the right hemisphere of the brain. Dr. Hughlings Jackson, whose guesses in neurology are more valuable, trustworthy, and enlightening than most other men's lifelong observations and carefully reasoned conclusions, long ago suggested that in epilepsy with the dreamy state the first spasm or abnormal condition would be observed on the left side of the body corresponding with involvement of the right or more subjective of the two hemispheres of the brain, and these three cases are, as far as they go, corroborative of his view.

In the fifth place I would ask you to note in this family chronicle that in two cases the impression of looking from a height was apparently influential in inducing cerebral disturbances of the kind which begins in dreamy mental states and culminates in epilepsy. In one case the first epileptic fit occurred when falling water was being looked at from the edge of a precipice, and when unusual ocular movements were therefore rapidly taking place; and in the other dreamy mental states were brought on by the mere remembrances of the agitation caused by looking down from an altitude.

(To be continued.)

TESTIMONIAL TO MR. BARNARDO, F.R.C.S. EDIN.

It is felt by many who are interested in the practical side of social philanthropy that the occasion of Mr. Barnardo's fiftieth birthday should not be allowed to pass without some recognition of the services which he has rendered to the cause of humanity by his work in the rescue and care of waif and destitute children. With this object in view, a movement has been set on foot to promote a jubilee testimonial to him, and we are asked to say that cheques may be forwarded to the Bankers, Messrs. Barclay, Bevan and Co., 1, Pall Mall East, S.W., with whom an account has been opened by the committee, whose names are as follows: Lord Brassey, Lord Kinnaird, Lord Polwarth, the Archdeacon of London, Colonel Howard Vincent, M.P., Mr. Samuel Gurney Sheppard, and Mr. Howard Williams.

The Croonian Lectures,

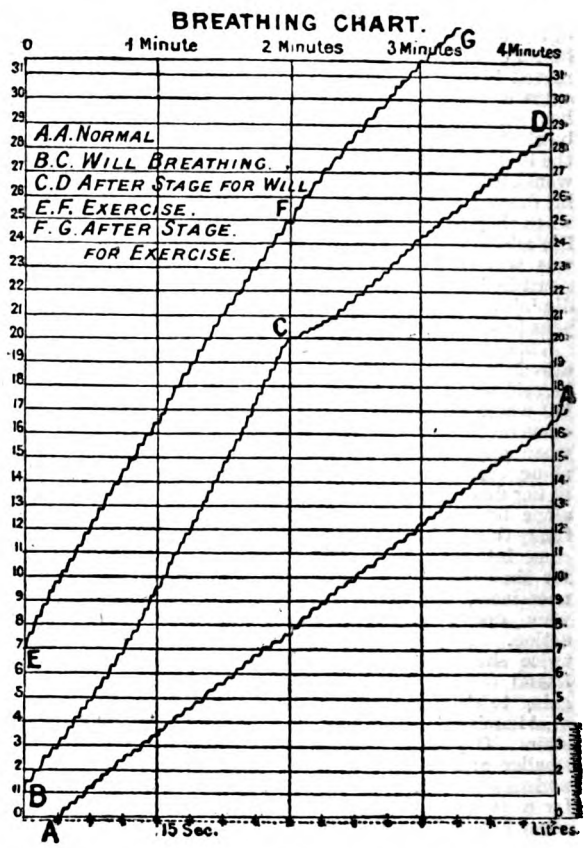
BEING A

CONTRIBUTION TO THE HISTORY OF THE RESPIRATION OF MAN.

Delivered before the Royal College of Physicians of London on June 18th, 20th, 25th, and 27th,

BY W. MARCET, M.D. EDIN., F.R.C.P. LOND., F.R.S.

LECTURE III.[1]



Delivered on June 25th.

MR. PRESIDENT AND GENTLEMEN,—In my last lecture the first three forms of breathing were considered; let us now proceed to the fourth, which applies to respiration under the influence of volition; but before doing so allow me to recall the remarkable experiment of Professor Mosso of Turin. This gentleman constructed a metal instrument, a sort of glove, through which his fingers were inserted, with the exception of the middle one; with this finger he worked a weight up and down until the digital muscles concerned in the labour were completely exhausted; at this stage the muscular contraction was carried on by means of electrical excitation, and he found that if, after a short period, the excitation was discontinued the finger was able still to maintain its work, showing that the muscles had not ceased contracting from actual fatigue, but from exhaustion of the will which had been exercised to move them.

There is an interesting borderland between psychology and physiology which is narrowing daily. The discovery of the electrical excitability of the brain by Fritsch and Hitzig, and of the motor centres by Ferrier and Yeo, followed by Horsley and Schäfer, has opened altogether a new field of research and brought the mental and physical functions nearer to each other. We do not know much of the physical effects exerted on the body by the perception of our senses. Moleschott, as far back as 1855, showed that from one-tenth to one-fourth more carbonic acid was exhaled by frogs under the influence of light than when in the dark, and also that this increase varied directly as the intensity of the light, which acted through the eyes and skin. It occurred to me that, if light exercises a distinct physical action on the living body, perhaps sound would produce a similar effect; but even a fairly loud sound, such as that produced by the beating of a gong close by, gave no positive result, the carbonic acid emitted under the influence of the sound being sometimes a little more and sometimes a little less than normal, and the same could be said of the oxygen absorbed. There was, however, a slight excess of air breathed (expired) while the noise was continued, which varied from 0·036 litre to 0·733 litre per minute in eleven experiments; and this slight excess was balanced by a corresponding diminution of the volume of air exhaled during the first five or six minutes after the sound had ceased.

The perceptions of our senses are certainly independent of our will, still the sight and hearing may not be entirely unconnected with volition; or it would, perhaps, be more correct to say that objects may act on the brain through sight, and sounds through hearing, without producing any corresponding impression. Take the case of a person lost in a brown study, he does not see objects though with eyes wide open, nor will he hear a sudden noise. By submitting our senses to the exercise of volition we train them and improve their perception. Thus we train the sight to the better appreciation of the beauties of nature. Those thrilling descriptions of Alpine scenery must be the outcome of the training of the sight to the thorough enjoyment of mountain views. The rapture into which Sarasate and Joachim throw their hearers requires a certain training of the audition. Mosso has shown that volition is a cerebral act attended with fatigue. I need hardly remind you of the fatigue experienced in listening to good music; two hours thus employed will, as a rule, be amply sufficient, and it often happens that in less time the attention begins to flag and the impression to subside. Operatic music may be listened to much longer, for the obvious reason that in an opera the exercise of volition is distributed between two brain centres—those of hearing and of sight—instead of being concentrated on a single one, and is on that account less exposed to fatigue.

We now come to the influence of volition on muscular movements. There are instinctive muscular movements in which volition is not concerned—for example, those required to balance the body; but these have been acquired in the first instance by the exercise of volition or by training. Hence it appears that training is of fundamental importance in all muscular exercise, such training being at the same time applied to the *volition* excited by the cerebral motor centre concerned in any special form of muscular work. Learning to play on a musical instrument is certainly training volition quite as much as, if not more than, training the muscles. The surprising rapidity with which the fingers run over the notes of the piano in response to the will is also a case in point; although, if I understand rightly Dr. Bastian's views, contained in his book on "The Brain as an Organ of Mind," it is very possible that such training, especially in young people, should develop a certain set of nerves through which these rapid impressions are conveyed, becoming automatic in their character. We shall see that volition has a direct action on respiration, hence training volition is at the same time training respiration. Let us now pass on to the subject which forms the substance of this lecture—the Influence of Volition on Respiration.

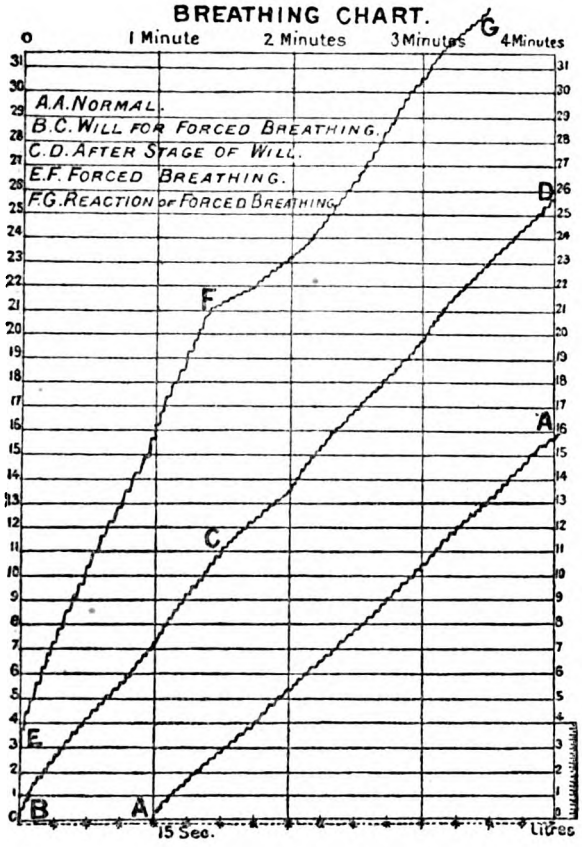
The tracing "under exercise" is shown to contrast with that of breathing "under volition."

Under ordinary circumstances, when sitting in repose, the mind is at rest as well as the muscles, and the breathing quiet and regular. Should a strong effort of volition be made, although unattended by any muscular contraction, it may be observed to react immediately on the respiration. If after a tracing of normal respiration has been obtained the person under experiment sets his mind to work and exerts his volition strongly towards carrying a heavy weight, running to catch a train, or pursuing another person uphill, the tracing

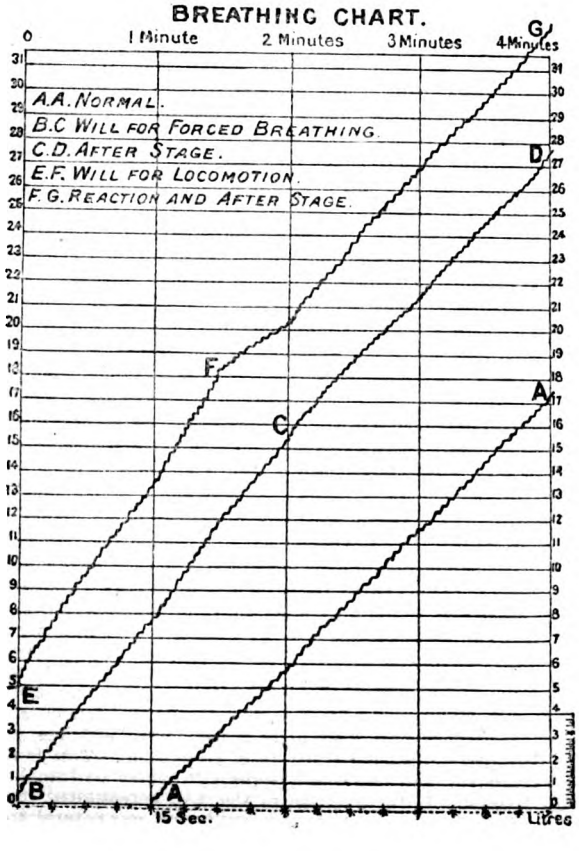
[1] Lectures I. and II. were published in THE LANCET of June 22nd and 29th, respectively.

Digitized by Google

recorded on the chart will be observed to ascend more rapidly than in the case of mental rest, showing a greater volume of air breathed in the same time. After, say, one or two minutes, let the influence of the will be withdrawn and respiration continued under mental repose, the first effect will be the production of a respiratory pause, the tracing taking a more horizontal direction, as seen in forced breathing, though perhaps somewhat less marked, after which the breathing will return to the normal, the tracing obtained being much like that of forced breathing. Similar experiments on different persons invariably yielded the same kind of curve on the chart. It follows that the influence of the will is to increase the volume of air breathed, and that on releasing volition a pause is produced very like that which follows forced breathing; but there is this difference with forced breathing, that when the will is applied say to the act of locomotion the increased pulmonary ventilation is absolutely automatic, while forced breathing is the direct effect of volition applied towards the expansion of the chest. An explanation of the pause or apnœa after forced breathing is that forced breathing produces an increased absorption of oxygen, and this oxygen, being used for the requirements of the body, lessens for a few seconds the calls for pulmonary ventilation. This idea suggested that perhaps such an accumulation of oxygen in the body might be employed by the muscles for a temporary increase of power. The following experiment was therefore made. While sitting in an armchair a weight of 10 lb. was alternately raised and lowered with the hand in keeping with the striking of a metronome, and to my surprise it was observed that after a succession of deep inspirations the weight could be raised a much greater number of times than after normal breathing; indeed, the increase of power was such that the weight could be lifted to the same height before exhaustion, perhaps two-thirds or twice as often after forced breathing as after natural respiration. For a time this effect of forced breathing was to me absolutely unaccountable, as there was no apparent call for an accumulation of oxygen in the tissues, and no proof of any such absorption; moreover, the excess of carbonic acid formed by the muscular power added was infinitely greater than could be accounted for from any excess of oxygen absorbed in the body. But perhaps in forced breathing there was really an excess of oxygen absorbed, which was taken up by the brain centres of forced breathing and gave "volition" the power of doing so much additional muscular work through increased respiration. This view was subsequently investigated and its correctness shown by experimental methods.



Allow me to quote the experiments which show to what extent muscular power may be increased by the preliminary exercise of "volition" exerted in the form of forced breathing. It might be added that, in order to succeed with these experiments, the attention, or "volition," should be given to the act. It failed once or twice when first tried, though successful on every other occasion with that same person, probably because the "will" was not applied with sufficient power or was not yet possessed of sufficient training for that kind of experiment.



Person under experiment.	Weight lifted.	Number of times weight lifted normal.	Time of forced breathing.	Number of times weight lifted after forced breathing.	Ratio of increase.

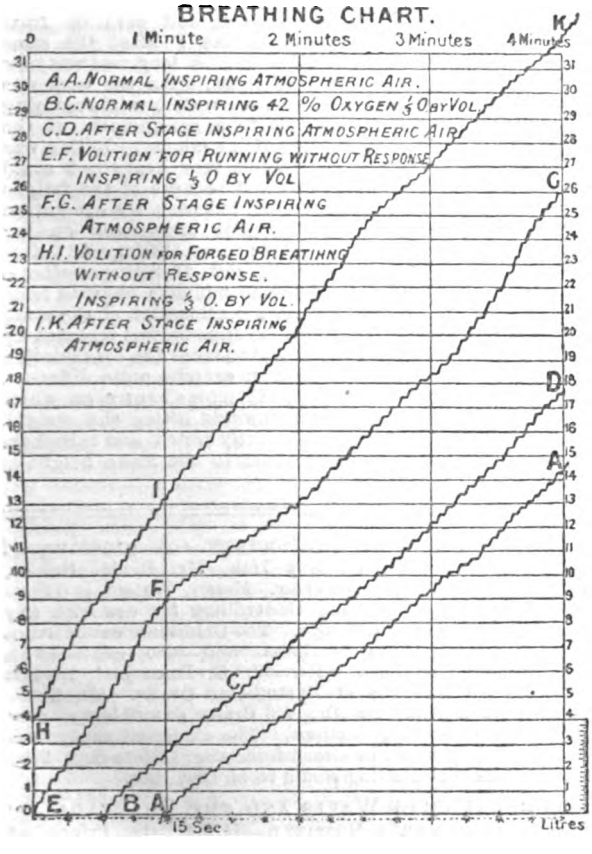
It is remarkable to what extent the arm becomes accustomed to this kind of work and can develop more and more strength with time from mere training. This is seen in the figures given later on, but it is important to observe that the present remark does not apply to the experiments taken singly, when the increased work was clearly due to increased power from a temporary cause. This point was set at rest by a very simple experiment. Two consecutive series of liftings were made without the intervention of any forced breathing. The weight was lifted till stopped by exhaustion 26 times in the first series and 26 5 in the second; hence it cannot be said that any influence of training was exerted in the comparative experiments. The effect of forced breathing in increasing muscular power can be tested by anyone while sitting quiet in his own room. My friend Dr. Louis Parkes lifted a weight of 8¼ lb. fifty times while in a state of physical and mental repose; and after forced breathing for one minute and a half, applying his mind to the act, he raised the same weight to the same height 125 times. A lady reclining in an armchair lifted with her right arm a tea-kettle weighing 4 lb. 13 oz. sixty times, and after resting ten minutes and breathing forcibly for one minute raised the same tea-kettle 100 times to the same height. The greatest effect was produced on a medical friend, who after ordinary breathing lifted a weight of 4 lb. 203 times in succession, and after a rest and forced breathing for two minutes lifted the same weight the same height no fewer than 700 times. In this case volition taxed the muscles to the utmost, and the arm remained tired and stiff for some days afterwards. The weights in all these experiments were lifted under natural or automatic respiration after forced breathing had been discontinued.

The absorption of an excess of oxygen in the body under forced breathing was so far an assumption, and it became necessary to determine experimentally if such were the case; the methods in use for the determination of carbonic acid and oxygen in the expired air being extremely delicate, the results obtained may be looked upon as thoroughly reliable. The experiment was undertaken in the following way. After resting for some time in the armchair the expired air in normal breathing was collected for subsequent analysis, then forced breathing was taken for about two minutes and the air expired collected separately. As soon as the appointed time had elapsed a signal was given, and the person under experiment relapsed suddenly into automatic breathing, while at the same time, by means of a three-way stopcock, the air expired was diverted into a third receiver, breathing being continued until it had come back to its normal condition in repose, which took place within six or seven minutes. There were thus three samples of air for analysis. The volumes of air inspired in each stage were calculated, as previously explained, from the nitrogen found, which underwent no change; the volume of nitrogen obtained yielding by a simple proportion the volume of air inspired. The difference between the volumes of air inspired and expired (after the application of a correction for carbonic acid emitted from the blood, into which subject it would take too long to enter at present) gave the volume of oxygen absorbed, and it is the excess of this oxygen absorbed in the body in forced breathing over the oxygen absorbed in normal respiration which concerns the present question. In eight experiments the increase per minute above the normal of oxygen absorbed under forced breathing, or rather under volition for forced breathing and response, varied from 0·8 to 36·4 c.cm., with a mean of 13 9 c.cm. (53 0 c.cm. mean absorbed normal, and 67·3 mean absorbed under forced breathing). At the same time the volumes of air expired were greater under forced breathing by 69 per cent. of normal. Therefore, in these experiments considerably more air had been inspired, and there was a marked increase of oxygen absorbed. If the excess of oxygen absorbed in forced breathing has for its object the exercise of volition, surely this absorption must take place in the motor centres of the brain concerned in forced breathing, and therefore in the medulla oblongata. So far the argument stands thus. Forced breathing is accompanied by an excess of oxygen absorbed in the body and leaves in its wake increased muscular power, but this excess of oxygen absorbed is very insufficient to account for the increase of carbonic acid produced, hence it does no such thing. Nothing, therefore, is left to explain the excessive development of power but an increased effect of volition, brought about by the absorption of an excessive amount of oxygen in its motor centre, which is, in the present case, the motor centre of respiration. This is a new departure, and one which appears to me to be fraught with interest. If the exercise of the will necessitated the absorption of oxygen in forced breathing, it was natural to conclude that the exercise of "volition" for forced breathing,

Digitized by Google

though without response, would be attended by a similar result; and, if so, it should also produce an increase of muscular power as observed after forced breathing. This reasoning gave rise to the following experiment. When in a state of mental repose I lifted a weight of 10 lb. 42 times to a height of 18 in., after which the arm became too tired to continue the work. After a sufficient rest, the will was applied to forced breathing, but without response, for two minutes; and on suspending its action I was able to lift the weight 76 times, being an increase of 34 liftings. A similar experiment with another person gave 70 liftings for normal, and 96 after the exercise of volition towards forced breathing without response; therefore, in both these instances the increased development of muscular power was clearly the effect of volition only. The proof that the effort of volition in the present case was unattended with response is to be found in the form of the tracing obtained.



When volition attended with response is exerted towards forced breathing the record on the chart invariably shows a pause or state of apnœa on returning to automatic breathing in repose; but when volition towards forced breathing is unattended with response there is no pause, or the pause is barely appreciable, as seen in the above charts. The same experiment was repeated with volition applied to various other forms of exercise, and an increase of power was invariably obtained; thus after volition for running without response I raised a weight of 8¼ lb. seventy-seven times against forty-seven for normal. This increase of power must have been produced through the agency of the respiratory centres, as, whatever be the form of volition, it must supply the oxygen necessary for the heat required towards the increased muscular exercise.

If, after exerting volition without response greater development of muscular power is obtained in the same way as when exerting volition towards forced breathing, and if the latter is, as I have shown, attended with an increased absorption of oxygen, it appeared probable that an excess of oxygen would also be absorbed under volition, though without response, exerted towards various forms of muscular exercise, and a number of experiments were made which showed most conclusively that such was the case. In a first series of seven experiments, the will being applied without response to running or rowing, the excess of oxygen absorbed in four of the seven experiments varied from 7·7 c.cm. to 19·4 c.cm. per minute, with a mean increase of 12·4 c.cm. per minute, while in two of the other three there was a slight decrease in the volition stage by 2·1 c.cm.; one of these, however, showed an increase in the after-stage, as if in this case the oxygen in excess had been taken in the first instance from that in store in the muscles and other tissues, and returned from the atmosphere on the resumption of mental repose. On releasing volition and relapsing into normal automatic breathing, the mean oxygen absorbed was less than normal, the deficiency compensating very nearly the excess taken in under volition. Therefore, after the phenomenon was over, the absorption of oxygen had apparently undergone no change or combination in the motor centre. The oxygen absorbed was now determined on three different occasions after applying the will without response towards lifting a heavy weight; the results in these cases were well defined. In one experiment the excess of oxygen absorbed per minute under volition was 15·6 c.cm., in another 13 8 c.cm., and in the third 35 8 c.cm., with a mean of 21·7 c.cm. The oxygen absorbed in the after-stage again very nearly compensated the excess under volition. This series, though consisting of only three experiments, therefore confirms the former in every way and shows that volition towards lifting a weight causes an accumulation of oxygen in the body—clearly in the motor centres of the muscles of the arm. A third set of six experiments was made by applying volition without response towards forced breathing. The increased absorption of oxygen in the volition stage varied from 1 5 c.cm. per minute to 48 0 c.cm. per minute, with a mean of 23 9 c.cm., and this excess was also nearly balanced by a corresponding diminution of oxygen absorbed in the after-stage. Probably these experiments, in which the oxygen determined "as absorbed" is taken from the air, do not show the total volumes of oxygen absorbed by the motor centres, as it is impossible to ascertain how much is supplied from the tissues. It thus appears that whenever volition is applied towards any form of exercise there is an absorption of oxygen in the cerebral centres concerned in the

Digitized by Google

phenomenon; and apparently with an excess of oxygen absorbed more work can be done than if the excess be wanting. The following experiment, in which a mixture of oxygen gas and air was breathed, is a striking confirmation of this view. The author lifted a 10 lb. weight forty-one times before being exhausted. After a rest he exercised his volition strongly towards lifting a weight for one minute and a half, and then raised it sixty-one times in succession. Again, after another rest, he exercised the same kind of volition as before, while inspiring a mixture of two-thirds of air and one-third of oxygen, containing nearly 43 per cent. of oxygen, instead of 20·9 per cent. as in atmospheric air, and immediately afterwards lifted the weight eighty-seven times before being arrested by fatigue; therefore under the influence of volition and air twice as rich in oxygen he could lift the weight twenty-six times oftener than when inspiring atmospheric air, the will being applied in a similar manner. This experiment repeated on another person gave with volition and atmospheric air seventy-seven liftings, and under the influence of volition and a mixture of air and oxygen, similar to the previous one, ninety-four liftings, or an increase of seventeen liftings.

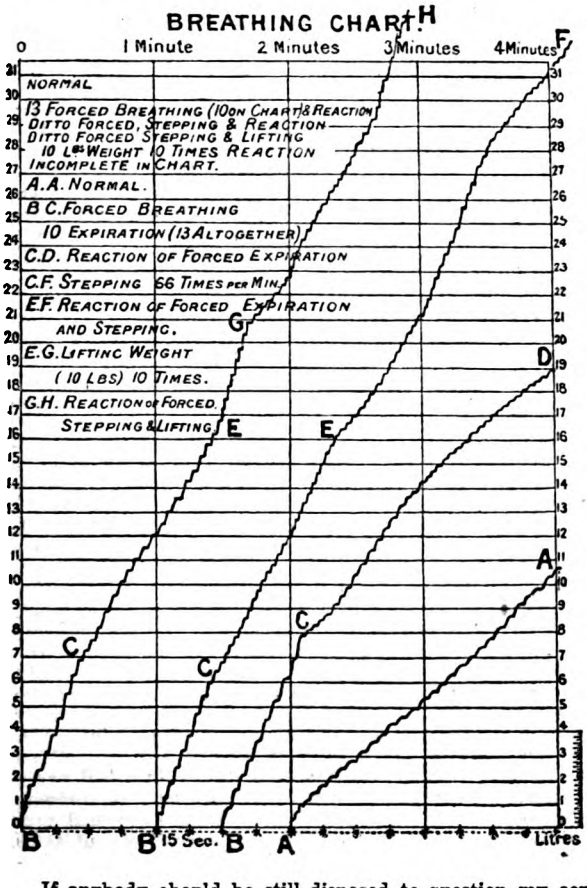
Returning to the respiratory tracings under the influence of volition, we find that, whether the will be applied without response to locomotion, to manual labour, or to forced breathing with response, the curve is about the same—that is, first

the tracing is steeper than normal, and then, on releasing volition, there is a pause, followed by another rise, showing an increased volume of air breathed beyond the normal. One tracing under volition differs from all the others: it is that for volition towards forced breathing without response, when the pause is altogether wanting or hardly visible. This pause at first appeared to be due to the accumulation of oxygen in the motor centre under the action of volition, but the absence of any pause in the records of respiration under volition for forced breathing without response, even after breathing air mixed with oxygen gas, showed the present view to be mistaken since this form of volition is also attended with an accumulation of oxygen in the respiratory centres. The only explanation I can now offer for this pause is the following. All the centres concerned in volition, whether they be the motor centres for locomotion or manual labour, &c., act on the centres of respiration; and when volition is accompanied by response a very large increase of breathing is produced, which is controlled by the requirements of the centres concerned. As soon as volition without response is arrested there is no longer any excess of pulmonary ventilation required, and normal automatic breathing follows; but before the centre of respiration has shaken off the influence of the other centres a short lapse of time intervenes during which the oxygen stored up in the tissues comes into use; this is the reason which appears to me to account for the pause, a view confirmed by the fact that, as shown in the breathing records, immediately after the pause there follows a slight but decided increase of air inspired beyond the normal, whose object would be to replace the oxygen taken from the tissues. Now in volition towards forced breathing without response, when the will is suddenly released no lapse of time is needed as there is only one centre concerned in the phenomenon—that of respiration; hence there is no pause, and the tracing returns immediately to the normal. Even if a mixture of two-thirds of air and one-third of oxygen be inhaled whilst volition is exercised towards forced breathing there is no pause; but a considerably increased pause is observed after inhaling the mixture of air and oxygen, and at the same time applying the "will" to other forms of exercise, as seen in the above chart.

It might be objected that the oxygen absorbed from the air in natural respiration is possibly liable to change every few minutes, and that the increase obtained under volition is due to some other cause than the exercise of the "will." In order to answer this objection the following experiments were made. Air was expired while in mental repose, and reclining in an armchair, in three successive bell jars, each receiver taking seven or eight minutes to fill. The three samples of air expired were analysed separately, and the experiment, being repeated on three different days, gave the following figures for oxygen absorbed per minute:

Cubic Centimetres of Oxygen absorbed per Minute.

Experiment I.	Experiment II.	Experiment III.
a—49·5	*a*—43·0	*a*—42 3
b—53·9	*b*—42·0	*b*—41·5
c—48·6	*c*—46·6	*c*—38 5



The greatest difference per minute in each experiment was therefore 5·3 c.cm. in the first experiment, 4 6 c.cm. in the second, and 3·8 c.cm. in the third, showing but little change in the oxygen absorbed in three successive experiments and giving much confidence in the method of analysis.

It may therefore be safely concluded that in the experiments on volition it was the effort of the will, and no other circumstance, which increased the volume of oxygen absorbed. Out of 24 experiments there were 3 with an increase of less than 1·5 c.cm. per minute and 2 with a decrease of 2 c.cm. The increase was marked in the other 19. In two series of experiments it amounted to 22 and 23 c.cm. There is no other way of accounting for that increased absorption of oxygen but through the agency of volition. Now, where can that oxygen go to in the body? It cannot remain in the blood, as hæmoglobin on leaving the pulmonary circulation is considered as charged with oxygen as it can be. On the other hand, there must be a demand for oxygen somewhere, because, as I have shown in my first lecture, no oxygen is taken into the body unless it be required. Of what use can be that oxygen taken in for the requirements of volition if not to exercise some sort of direct action on the motor centres concerned in volition? A parallel case would be the absorption of increased volumes of oxygen for the performance of muscular exercise, although the mode of action in volition appears to be of a very different character. The fact that oxygen is required in the body towards volition is shown by the increased volume of air breathed under volition. If this air was wanted for an excess of carbonic acid, we should find an increase of carbonic acid produced. There is indeed a very slight increase, but it is wanted for the extra work done by the muscles of respiration, and there may be some slight oxidation of hydrocarbon in the brain substance; in some cases it is impossible to find any production in excess of carbonic acid, this being probably due to physiological irregularities which it is impossible to control. We find, also, a certain volume of carbonic acid displaced from the blood by the

Digitized by Google

increased volume of the air breathed. It might perhaps be objected that out of twenty-four experiments five results failed to agree with the other nineteen; but these exceptions occurred in the early part of the inquiry, and volition had very possibly not been brought to bear so earnestly as it was in subsequent experiments. It is a fact that, the more experienced we became—my assistant and myself—in these volition experiments, the greater was the volume of oxygen which was found absorbed. There is evidence in favour of this view in addition to chemical analysis: this is increased muscular power, and I shall again beg to direct your attention to this phenomenon.

If additional power is given to the muscles by a preliminary effort of volition, naturally there must be an increased amount of carbonic acid produced in proportion to the increase of strength developed. Three experiments were made which showed clearly that such was the case. The mean relation of the strength developed was 1 to 1·300, and of CO_2 to CO_2 while engaged in the extra work was 1 to 1·396; there was not, therefore, much difference between those relations for such a small number of experiments. If after exercising the will, instead of returning immediately to the state of physical and mental repose the weight of 10 lb. be raised in the usual way for one minute, followed by repose, while a record of breathing is taken on the chart, the pause which has been checked by the exercise now appears, and afterwards respiration returns much increased in volume. Finally, if immediately after the exercise of volition for one or two minutes stepping exercise is taken for one minute, followed at once by a return to the sitting position, and lifting the weight, say, ten times in succession, on assuming the state of rest the pause will again appear, though perhaps less marked, and there will be for a time a considerable increase in the pulmonary ventilation beyond the normal in repose. This is clearly seen in the subjoined chart recording the experiment.

If anybody should be still disposed to question my contention that the increased muscular work in these experiments is due to the influence of volition, the experiment of Mosso showing that fatigue of "volition" suffices to arrest muscular contraction would go far to dispel any doubt in that respect. The following experiment, which I have not seen quoted, confirms remarkably Mosso's discovery, while at the same time it is a strong argument in favour of the view advocated in this lecture, and differentiates very clearly the motor centres of the brain. Let a person, while sitting in an armchair, raise a weight, as in the experiments related above, until his arm is too tired to continue the work. He then takes a rest in mind and body of, say, one minute, and again resumes lifting the weight as long as he can. The number of times the weight is lifted is counted in both cases. Next a rest is taken, perhaps, for ten minutes, and the same kind of exercise repeated until the arm is exhausted. At the expiration of that time the arm is placed in a state of repose, but the "will" continues being applied as strongly as possible towards the exertion of lifting the weight, and this is continued for one minute. At the end of that minute the weight is again raised with that same arm, when it is found to be so tired that it is not equal to raising the weight by perhaps more than about one-half the number of times the weight was lifted under precisely similar circumstances without the application of the will. If, however, during the interval of one minute between the liftings, the will be directed towards a different kind of muscular work, such as running uphill, on resuming the lifting, the arm is found to be fresh and rested, and can raise the weight the same number of times as if the mind had been at perfect rest for that minute.

The following are two experiments which illustrate the phenomena. While reclining in a deck chair I raised a weight of 10 lb. 49 times and gave up from fatigue; after resting for one minute I lifted the same weight to the same height 40 times. A long rest was now taken and the weight lifted 47 times, when the work was stopped by fatigue; then the arm was rested, while applying volition as strongly as possible to a continuation of the same effort of lifting for a lapse of one minute. Lifting was now resumed, when the weight felt very heavy and could only be raised 21 times—clearly not because of the fatigue of the muscles, as they were rested, but from the exhaustion of the power of volition. A similar experiment on my assistant gave the following results: normal liftings, 42; after one minute's mental and physical rest, 41 liftings; after a prolonged rest, 44 liftings; after one minute's physical rest, but with volition exerted towards a continuation of the same exercise, 31 liftings. The same experiment was repeated by both of us without applying the will towards the continuation of the same exercise, but towards an exercise quite different, such as running, thereby resting the motor centre on which volition had exerted its action towards lifting the weight. After a minute the arm felt perfectly rested and raised the weight the same number of times to the same height as before.

ROYAL MICROSCOPICAL SOCIETY.—A meeting of this society was held on May 15th, Mr. E. M. Nelson, Vice-President, being in the chair. Messrs. Watson and Sons exhibited a simple Centring Underfilling for use with any ordinary student's microscope. The Chairman exhibited a new Low-power Lens by Zeiss, and also exhibited a new Photographic Lens. Mr. W. C. Bosanquet, read a paper on the Anatomy of Nyctotherus Ovalis. Mr. G. C. Karop read a paper by Dr. A. Bruce describing a new Microtome for cutting Sections. The chairman announced that the library would be closed from Aug. 12th to Sept. 9th, and that the next meeting would be on Oct. 16th.

THE PRINCE OF WALES AND THE SHAHZADA AT ST. BARTHOLOMEW'S HOSPITAL.—H.R.H. the Prince of Wales, the President of St. Bartholomew's Hospital, on Friday afternoon last visited the institution, accompanied by the Shahzada. The visit was private, and but few of the public were present at their arrival. Having passed through the gateway of King Henry VIII. they entered the quadrangle, where they were greeted with loud cheers from large numbers of students and the members of the staff. All those patients who could be safely brought out had been thoughtfully accommodated with seats and couches in the square, where they were able to get a good view of the Royal visitors, and, as they waved their handkerchiefs and cheered, the Prince of Wales and the Shahzada smilingly acknowledged their welcome. The governors of the hospital had assembled in the large hall, and after their reception the Royal visitors proceeded to view the various wards in the hospital as well as the new theatre. The building had been suitably decorated for the occasion.

ABSTRACT OF AN

Address

ON THE RELATIONS OF SCIENTIFIC TO PRACTICAL WORK IN THE UNIVERSITY OF CAMBRIDGE.

Delivered at the opening of the Summer School of Medicine for Qualified Medical Practitioners, at Cambridge, on Monday, July 1st, 1895,

BY SIR GEORGE MURRAY HUMPHRY, M.D. CANTAB., F.R.C.S. ENG., F.R.S.,
PROFESSOR OF SURGERY AT CAMBRIDGE UNIVERSITY.

GENTLEMEN,—To me, as senior member of our teaching staff, has been assigned the pleasurable duty of welcoming you to this ancient and delightful seat of learning so full of interests and opportunities of various kinds. Here all, or nearly all, the branches of science are cultivated and taught, cultivated and taught in as free, open, and genial a spirit as the laws and restricting prejudices of our country permit. Here men and women are seeking education when minds are most plastic, when impressions are quickest and most durable, at the important time of life when growing freedom from restraint exercises, and needs, growing self-control, and when the mental training most requires to be balanced and furthered by corresponding training of the energies and vigour of the body. To have lived and moved for more than half a century in such a place, and taken during the whole of that time an active part in its work, and to have been associated with and stimulated by the gifted men similarly occupied, has, you may suppose, been an inestimable privilege for which I cannot be too thankful. I came here reluctantly, simply as a professional bread-winning duty, with no thought of taking part in university work, and would have contentedly gone away had I failed in my object of obtaining the surgeoncy to the hospital; but I soon learned to appreciate and enjoy the great and special advantages of the place; and you may judge what a pleasure it has been to see these advantages gradually developing and increasing, to witness the removal of all religious, or rather ecclesiastical, restrictions without the weakening, rather with the strengthening, of religious feeling, to watch the gradual increase of the area of study and teaching, to note the liberality of the university, exercised to the full extent of its limited but inadequate means, in building laboratories, museums, and workshops, and in providing professors and other teachers in the several branches of science, and, lastly, to see medicine taken so fully and generously within the university range, and the medical school placed upon a flourishing and, I hope, assured basis.

The two old universities were from an early period regarded as the special seats of the higher learning and the more intellectual cultivation. To this feeling with regard to them they probably owed the Royal patronage and countenance which gave them charters and other privileges, and which discouraged the foundation of similar institutions in other parts of England, it being thought better to concentrate the teaching power in these two places than to diffuse it elsewhere. To this feeling were due the donations and bequests by which the colleges were founded and enriched, and also made the means of conferring those social advantages which are to be found in no other places in the world. To live up to this estimate of being the seats of the higher learning and the higher education must be the great effort and ambition of the universities at the present time and in the future. The doing this becomes increasingly difficult as the stream of time bears upon us and floods us with an ever-increasing amount of material which has to be sorted, analysed, and appropriated, and which throws so much labour upon the teaching and the acquisition of recognised facts that little time is left for that real appreciation of them in which higher study consists. Doubtless the old, and to some extent the modern, ideal of the higher learning and the higher perceptions was based upon the study of the literature and art of the ancient Greeks, in whom thought could deal with and dominate over fact, in whom the mind was comparatively free from the trammels of the surroundings, in whom the appreciation of beauty of form was not hindered by detail of structure, and in whom the intellectual energies were not diverted from philosophical thought by the necessities of what we may fancy to be a more civilised, and which is certainly a more complicated, life. At present in the study of a science the mind is so choked by the in-pouring of facts that little room is left for reflection upon them. Knowledge of laws and principles has too much to give way under the pressure of accumulated details, and the higher, the more valuable, the more really mind-strengthening education is proportionately sacrificed. There can be no doubt that the examination system which rules over teaching in all our schools—primary, secondary, and university—is partly accountable for this. A knowledge of facts is more easily acquired and more easily and quickly shown and appreciated in an examination than a knowledge of principles. To state that a thing is we recognise to be far easier and more rapidly done than to state how or why it is. To give a chemical formula is easier and quicker than to give the principles illustrated by it. Many a man will flourish off the description of a bone without its having ever occurred to him to think of the purposes served by the conformation of its several parts, and the examiner usually requires no more. Hence the production and profitable sale of little cram-books, and the cramping of interest and intelligence and enjoyment in study. How terribly serious is this. How greatly has it increased since the halcyon days when I began and throughout my pupilage enjoyed the study of medicine, when I felt no thraldom of examination, when an hour of *vivâ voce* at the college was all that was needed, and cram-books did not exist.

To turn the wheel of time back and revert to the old ways, however good and pleasant they may have been, is impossible. We must march ever on. It is useless to try to stop the course of events. Facts must grow and examinations must continue, and, I fear, become more stringent and more crushing of freedom and pleasure in study. Still, it must be the great duty of the universities to meet these difficulties, to maintain reason and thought in their proper status, and to prevent their being weighed down and stunted by fact-cramming and examinations. A great power and responsibility exist with examiners, for it is with them to set not only the standard but the quality of the knowledge required; and one cannot but feel that by demanding less range of study, but more depth of knowledge with clearer perception of laws and principles, they would do great service and would promote higher and sounder teaching and better learning. These remarks apply in their full extent to medicine. Let it be remembered that we are not better than our forefathers, that none of us are wiser than the wise men of old, that mental power is not increased by the new ideas and new discoveries handed down to us. These have added immensely, especially of late, to our means and opportunities, but not to our ability in employing these means; and experience tells me that the ground over which the medical student has now to travel is too much for him, and rather jades than strengthens him. My effort, too often, as I think, ineffectual, has always been to curtail the syllabuses and lessen the number of subjects which are required of him; and when I was a member of the General Medical Council I always resisted the tendency to demand of him special knowledge of special subjects, because I felt that the more that tendency was yielded to the less likely would he be to acquire a sound and intelligent knowledge of the great principles which lie at the root of the whole science and practice of medicine. I desired to see the preliminary subjects made simpler, easier, narrower in range, more thought-inspiring by the inculcation of principles, more truly educational. I am sure that the student would thus be better fitted than he now is to enter thoughtfully upon the ground of medicine proper, better prepared to dig deeply into its most fertile soil, better prepared to interest himself in, and exercise his reason upon, the many facts which medical science affords. Far be it from me to detract from the practical study of medicine. My life has been mainly spent in it, and I regard it as supreme and more important than any other subject. I can little sympathise with the learned mathematician who drank to the toast of "Pure Mathematics, the Science which has never been degraded by Practical Application." But I have ever felt it to be the business of the university in an especial manner to associate scientific study with practical work, believing that thus the best practitioners are made, and knowing that the men who have stood foremost in our profession have ever signalised themselves as the chief cultivators of its science. Human anatomy is a good example of what I mean, not only on account of its high practical value and its direct bearing on diagnosis and operative surgery, but also as being

Digitized by Google

a medium of cultivating accuracy and attention and reflection upon the physical construction of the human body, and the adaptation of its parts to the purposes they have to serve. A fact in anatomy, as I tell my pupils, should be regarded as a peg to hang a thought on, and without the thought it loses much of its interest and educational value. Physiology and pathology are linked together in disclosing processes, healthy and morbid, as well as the deviations of the morbid from the healthy; and they, together with the investigation of the Therapeutical means by which the morbid processes are to be brought back to the healthy, carry us into Alpine and difficult heights of experimental and philosophical science, in climbing which the energies of many ages will find ample scope. In Morbid Anatomy, Medicine, and Surgery, where we deal with the results of these processes upon the fluids and solids of the body, with the symptoms to which they give rise and their treatment, and the relations of causes and effects, we find problems which long have, and long will, occupy the minds and call forth the skill of thoughtful and keenly observing men. Indeed, medicine is so vast, so difficult, and in its practical bearing so important, a science, making, perhaps more than any other science, so great demands upon body and mind, that too much attention cannot be paid to the education for it.

We have invited you, Gentlemen, to come and consider with us for a short time this great subject of medicine from a university—that is, as I have before said, from an educational and a higher learning—point of view—the point of view from which it and every subject taught in this place should be considered. We shall be glad to have your opinions and to hear your criticisms, for those who are in the busy struggle of professional life can form good judgments as to the best means of equipping for it; and assuredly in the matter of teaching we have yet much to learn. We propose to take you back, in a measure, to school life and school thought, and demonstrate in our laboratories some of the new methods which the quickly advancing work of the last few years has brought about, with their practical applications. There will also be demonstrations of specimens from the Museum of Morbid Anatomy; and there will be demonstrations of cases at the hospital, as well as special lectures by the Regius Professor of Physic and, I wish I could add, the Professor of Physiology. You will see, therefore, that our object is to connect scientific and practical work, to make your brief sojourn here not, as might be supposed, a festive but a really working period, a period for observation, study, and mutual instruction. At the same time, it would scarcely have been in harmony with the spirit of the place if we had forgotten the great principle conveyed in the aphorism, "Otiare quo labores." Accordingly, opportunities will be afforded for visits to the colleges, and there will be a garden party in the Fellows' Garden at King's College to-morrow afternoon, at which members of the *séance* and ladies accompanying them will be welcome. We had some hesitation about attempting this new departure in the present summer, feeling that the great attractions of the meeting of the British Medical Association in London would divert so large a proportion of those who can spare a short time from the pressing requirements of medical practice; but we determined to take courage while the spirit was upon us, and to carry out our plan if a few only expressed their willingness to come. We relied upon the interest common to the members of our profession in the advancing science of medicine—an advance which has been greater in recent years than in any former corresponding period. The response to our invitation has proved that we are not mistaken. It has shown that the proposal was generally acceptable to the members of the profession, though many, of course, could not avail themselves of it. I trust you will not be disappointed.

I must not omit to mention the willing and generous manner in which the professors and their assistants have rendered us their aid by opening the laboratories, making the requisite preparations, and giving up their time, in some instances at much personal sacrifice. Their reward will be in your appreciation of, and profit by, their efforts. Our thanks are also due to the authorities of the colleges, who, with their accustomed liberality, have placed their rooms, dining-halls, and kitchens at our service; and our thanks are pre-eminently due to our honorary secretary, Dr. Griffiths, upon whom the arrangements have almost entirely devolved—no light task. His energy and organising ability have, however, proved equal to the occasion, in spite of the distractions—the not inconsiderable distractions—preceding and attendant upon an interesting and important ceremony which took place a few days ago, and the curtailed honey period consequent on it. You will, I am sure, join in hearty congratulations and good wishes on that auspicious event, and also on the fact of his having been this day elected to the surgeoncy of Addenbrooke's Hospital.

I will detain you, Gentlemen, no longer, for you will find in the next room matters more worthy of attention than I can give you. Yet there is one thing further to which, with much regret, I must allude. This morning's papers have told you of the great loss which England and the world at large, more especially the world of science, have sustained by the death of the Right Honourable Professor Huxley, which throws a chill of sorrow over us all. Few persons were gifted with his ability in investigation, with his reasoning power and his power of putting his thought into clear, vigorous, incisive words, whether as a speaker or a writer. He was in the foremost rank of men, and would have been so whatever line he had chosen to take; and in many directions might have gained far more material wealth than in that which he chose to follow. In the last speech I heard him make, at the Royal Society dinner, he told us that an influential relative urged him when he was a young man to go to the Bar, feeling that his talents would find their scope there, but he replied that "his desire was to work out and state truth, not to conceal or pervert it." This was the key-note of his life—kind, genial, humorous, a warm and steadfast friend, loved by those who knew him well, he was stern, even fierce, as a champion of truth. Still, though he might hit hard there was no malice in his blow, and he was respected by opponents as well as followers. All things come to an end, but the good and evil that men do live after them. Huxley leaves much of the former, but, so far as I know, none of the latter, behind him. This sad event necessitates an important change in our evening programme which all of us much regret. Our Professor of Physiology, Dr. Michael Foster, from whom we anticipated the lecture he had kindly promised to give on Wednesday, who was endeared to Huxley by long friendship and many ties, will, we fear, not be free to address you, which I need scarcely say is no small disappointment.[1]

THE PARASITE OF MALARIA AND MALARIAL FEVERS.

[WITH COLOURED ILLUSTRATION.]

BY GEORGE THIN, M.D. ST. AND.

THE remarkable progress of scientific medicine in recent years is characterised by three great discoveries, and in each case by the discovery of a parasite. The mysteries of leprosy and tuberculosis were unveiled by Hansen and Koch, who have shown that the pathological changes peculiar to these diseases are due to bacilli which are essentially distinct, though they have many superficial features in common. Not less remarkable, and certainly of not less practical importance, is the great discovery of Laveran that malarial fever, the perennial scourge of many of the most densely populated countries in the world, is due to an animal parasite, a hæmatozoon, which lives in and destroys the blood of its host. It is difficult to estimate the extent of the destruction of human health and life caused by this minute creature. As a cause of death and of illnesses that undermine the health, it is the predominant factor in populations which in the aggregate can be counted by hundreds of millions. The blood tax which it levies on the inhabitants of the temperate zones who enter the tropics renders the maintenance of our Indian empire onerous and costly, whilst it makes the colonisation of many rich and fertile countries an impossibility. Only those who have lived in fever-stricken countries can form a conception of the extent to which happiness and success are influenced by the poisonous and exhausting effects of this parasite. It was thus to be expected that Laveran's discovery would stimulate the investigations of the Italian pathologists whose close attention had been long given to the malarial fevers which prevail so largely in the peninsula, and it is in Italy that additional facts of great importance regarding the parasite

[1] We learn that the change was not necessary, and that Dr. Foster was able to give his lecture as had been arranged.

Digitized by Google

and its effects have been discovered and appreciated. It was, therefore, to many of us one of the attractions of the International Medical Congress at Rome last year that an opportunity was given of coming into closer contact with the important work which was being done there in connexion with these fevers than was otherwise possible. In addition to the usual papers and public demonstrations, Professor Marchiafava and his assistant, Dr. Bignami, gave up their time with untiring courtesy to those who, like myself, desired to obtain more detailed information than could be given in the sectional meetings, and, what has been of much importance to myself, they placed at my disposal portions of brain and spleen from malarial patients which enabled me after my return to London to experiment with various dyes in order to satisfy myself as to the most successful methods of demonstrating the presence of the parasite in the tissues. This material has supplemented usefully the examinations of fresh and dried malarial blood which can be obtained in London. During the period which has elapsed since the Congress I have devoted much time to studying specimens of blood taken from the fingers of patients actually suffering from fever, and to staining and examining preparations sent to me from various malarial countries by medical friends. The results of this investigation will, I hope, be eventually brought before the profession. Meanwhile, I trust it will serve a useful purpose if I give the results of my experience regarding the best methods of demonstrating the parasite.

To begin with, I may remark that many good workers with the microscope have failed to see the parasite, and more than one of my friends practising in malarial countries tell me that they have not been able to find it. It is very desirable to appreciate the reasons of this failure, for there are several. First of all, of course, there is the difficulty of recognising an unfamiliar object, but in the present case I am satisfied that this has not been the chief difficulty. The malaria parasite assumes various forms and sizes. Some of these are so characteristic in shape and comparatively so large as microscopic objects that their recognition should present no difficulty to observers with ordinary training and ordinary instruments. Others, on the contrary, are so small in size, and so colourless, and are found for such short periods in the blood taken from the finger, that it is often very difficult to find them at all, and when they are present only a skilled microscopist would recognise them, and only excellent instruments would enable them to be distinguished. These latter forms are specially characteristic of many fevers which occur in the tropics, and that is one reason, I am satisfied, why some of my friends have failed to find them. They did not see them because they were not there at the time when they were looked for; and after a number of ineffectual efforts to observe the parasite in the blood of patients suffering from severe forms of fever the search was given up, although if it had been continued for a sufficiently long time at sufficiently short intervals the stage during which the small parasite could be seen would have been hit.

After Laveran's demonstration of the hæmatozoon came the remarkable and important observations of Golgi, who showed that tertian and quartan agues are due to special and distinct varieties of parasites, having different periods of evolution, and characteristic features which, with a little experience, can be readily distinguished under the microscope. The detection of the parasite in these two classical types of fever ought not to be difficult to anyone accustomed to use the microscope in ordinary clinical work and provided with ordinarily good microscopical apparatus. The tertian parasite during the second day of its development, when there is free pigment formation, and when it fills nearly the whole of the red corpuscle, is not a difficult object to see. Still easier is the detection of the quartan parasite in the later stages of its development, the large central block of pigment after spore formation has begun being a fairly conspicuous object. But the greater proportion of the fevers with which we have to deal either in England or in the tropical countries from which patients come are neither tertians nor quartans. It would indeed be strange if, with the comparative benignity of tertians and quartans, and the readiness with which their parasite is destroyed by quinine, many patients should be found who were not cured long before they reached our shores. In many parts of the south of Europe, in Africa, India, and other tropical countries fevers prevail which are more or less continuous or irregular, or approach regularity with long periods of apyrexia, in which the parasite (with the exception of one form to be shortly noted) is only found in blood from the finger in an early stage, disappearing so rapidly that its existence may easily be overlooked. Fortunately, for the purpose of diagnosis there is in these fevers the exceptional form to which I have alluded. I refer to the crescent-shaped body, so-called "of Laveran" (though why this particular form should be capriciously selected to bear the name of the man who made this immortal discovery, seeing that he saw and described all the other forms as well, is not very clear). The detection of the crescent-shaped body is easy—as easy, if not easier, than that of the fully developed quartan parasite, being found free in the blood, unlike in shape to anything else that occurs there, and being always marked by a central patch of pigment. In addition to these forms, of all of which my experience has been sufficient to enable me to speak with some confidence, I have observed in blood from fever patients sent to me from the West Coast of Africa a minute parasite whose characteristic feature would appear to be the rapid and early development of a small, central, comma-shaped mass of pigment previous to any sign of spore formation. Not having been able to study this parasite in stained preparations I shall have no more to say regarding it, except to add that in the specimens I examined high powers of the best kind were required.

The physician who seeks the aid of the microscope in the study and treatment of malarial fevers must also devote his attention to the appearances presented by the pigment which is found in the white corpuscles. There are cases of severe malarial fever in which repeated examination may fail to find the parasite in blood from the finger, but in which blocks of pigment in the leucocytes testify to the destructive work of the hæmatozoon in the internal organs.

These are the forms with which it is necessary to be familiar if we desire to treat malarial fevers on a scientific basis. The technique is not easy nor rapidly acquired, in this respect, unfortunately, differing much from that which is applicable to the study of the parasites of leprosy and tuberculosis. Having carefully tested the methods which have been recommended by recent writers on malaria, and having made many experiments in order to test the applicability to this study of the procedures employed in histological work, I believe a short account of what may be attained by the use of those methods which I have found best will be useful to others who are working at this subject, and particularly to residents in the tropics, whose comparative isolation renders it difficult for them to test the various methods for themselves. It will be convenient if I treat separately, first, the literature which it will be found useful to study; secondly, the microscopical apparatus necessary; thirdly, the examination of the blood; fourthly, the use of dyes in preparations of malarial blood; fifthly, the staining and studying of sections; and sixthly, add a few remarks on the clinical aspect of the question suggested by the experience of the cases which are seen in England.

1. *Literature.*—The bibliography of malarial fever since the discovery of the parasite has already become fairly extensive. Fortunately, all that is essential for the beginner can be found in small compass. As an introductory work I recommend in the first instance Laveran's book, "Paludism and its Hæmatozoon." The clearness and simplicity of style of this work, its lucid descriptions of the parasite, and the excellent illustrations render it, in my opinion, eminently fitted to interest the reader in the subject. After that comes the useful manual of Mannaberg, "The Parasites of Malaria." This observer has arranged in a systematic form all the knowledge that has been obtained regarding the parasite up to a recent time. He has thoroughly digested the literature bearing on it, has himself added much that is important regarding the minute structure of the parasite, and has offered suggestions regarding certain phases in its development of an attractive and suggestive kind. The numerous and well-executed coloured figures in the four plates which are appended to the book are indispensable to anyone who wishes to pursue the study in its more scientific aspects. It also contains much useful information regarding the technique which it is necessary to acquire. Both these works being translated for the Sydenham Society are available for English readers to whom the French and German languages present difficulties. To many readers Mannaberg's work is almost indispensable for another reason. I know no other book written in English which gives so good an account of the remarkable observations and theories of Golgi, an acquaintance with which is necessary

Digitized by Google

to anyone who attempts to bring his knowledge of malaria abreast with the results of recent work. None of the summaries of Golgi's papers which are known to me, however, take the place of the original papers of that observer. To those who can read the languages in which they are written I specially recommend the paper published in the *Fortschritte der Medicin*, No. 3, Feb. 1st, 1889: "Ueber den Entwickelungskreislauf der Malariaparasiten bei der Febris tertiana, Differentialdiagnose zwischen den endoglobularen Parasiten des tertianen und denen des quartanen Fiebers," in which it is clearly shown that tertian fevers are caused by a special variety of the parasite, and the points of difference between the tertian and quartan parasites are pointed out. Golgi's original drawings, showing the various phases of these parasites, which have been so often copied since (and not always advantageously), are found in the plate which accompanies the memoir. The *Zeitschrift für Hygiene*, vol. x., 1891, contains his paper on the "Development of the Amœba Malariæ Febris Quartanæ as Illustrated by Photographs." Twelve photographs from blood preparations of quartan fever are printed, in which the size of the quartan parasite and the amount and grouping of pigment which are characteristic of it are demonstrated. The action of quinine on the parasite in its various stages of development is discussed in a paper in the *Deutsche Medicinische Wochenschrift*, 1892. Nos. 29–32: "Ueber die Wirkung des Chinins auf die Malariaparasiten und die diesen entsprechenden Fieberanfälle." Two other papers by Golgi specially deserve study because they apply to forms of fever regarding which our knowledge is still very defective. I refer to a paper on intermittent malarial fever with long intervals, published in the *Archivio per le Scienze Mediche*, vol. xiv., N. 14, under the title: "Sulle Febbri Intermittenti Malariche a Lunghi Intervalli." It is written in Italian, and I am not aware that it has been translated. The other paper, written in French, is on the malarial summer-autumn fevers of Rome: "Sur les Fièvres Malariques Estivo-Automnales de Rome: Lettre du Dr. C. Golgi au Prof. G. Baccelli" (Turin: Hermann Loescher, 1894). This last paper should be read in conjunction with the valuable work published by Marchiafava and Bignami on the "Summer-autumn Fevers of Rome,"[1] which contains a large number of observations on the severe and pernicious fevers which occur at that season in the Roman Campagna. The writers have attempted to reduce these fevers to a system based on the leading idea that they are caused by parasites which they distinguish as malignant tertian and quotidian, the latter having two varieties, a pigmented and an unpigmented quotidian parasite. This work is a storehouse of facts, is admirably illustrated, and its study is indispensable to observers who are engaged in the investigation of tropical fevers. The opinions of the writers have been criticised on clinical grounds by Baccelli, and their observations have been recently reviewed by Golgi in the light of observations made by himself in Rome in the summer and autumn of 1894. In his published letter to Baccelli, Golgi not only shows how far we yet are from possessing an accurate knowledge of the forms of the more malignant parasites whose development takes place in the internal organs, but indicates in a very suggestive manner the lines on which subsequent investigations should take place. The study of Marchiafava and Bignami's work should be followed by that of Golgi's "letter."

It is to be desired in the interests of the medical men who practise in malarial countries that translations of Golgi's papers should be provided for their use. They are too important to be taken at second-hand, and do not receive full justice in the necessarily brief notices which have been given in the more accessible works, but a fair knowledge of their scope can be obtained by reading Mannaberg's Manual.

2. *Microscopical apparatus.*—Although it is possible to see the larger forms of the malarial parasite with an ordinary dry objective of moderate power, its satisfactory study, even that of its larger forms, requires high powers and immersion objectives. This will be evident from a comparison of the drawings made to scale, which I have given in illustration of the next divisions of my subject. Although the observer who has at his disposal a good magnifying power of 500 diameters need not despair of using it successfully, even for purposes of diagnosis, one of the earliest results of its use will be to satisfy him of the necessity of providing himself with higher powers. A good water immersion objective is much better for this work than the dry lenses, but these again fall far short of the advantage to be had by using an oil immersion. Very fair objectives of this kind can now be had at a moderate price, but the cheaper the oil immersion the more necessary it is to have a careful selection made in purchasing one, for undoubtedly these cheap objectives vary considerably in excellence. Where a few pounds extra cost is not of importance I strongly recommend the use of an apochromatic oil immersion by a maker whose name is a guarantee of quality. The advantages which a good objective of this kind possesses are much out of proportion to the additional expense. A magnifying power of 1000 diameters is frequently desirable, and considering that this can only be attained by the use of a high eye-piece, which, of course, magnifies the faults of the objective, it is clear that only systems of great excellence can be satisfactory. An apochromatic oil immersion, then, is the objective which I recommend, and if with a compensating eye-piece, so much the better. But to use a system of this kind a good condenser and a stand to carry a condenser are indispensable, which at once excludes the use of the small Continental models which have so long sufficed for the wants of students in the elementary histological work of practical classes and for ordinary clinical work. For solidity and adaptability of position the English microscope stands are unsurpassed. The apochromatic condenser of Powell and Lealand is admirably suited to bring out the best qualities of an apochromatic oil immersion, and the general utility of the Abbé condenser is well recognised. I cannot too strongly urge those workers who intend seriously to take up this study to provide themselves with a good microscope stand, a good condenser, a good oil immersion, and by preference an apochromatic oil immersion.

3. *The examination of the blood.*—The technique of the examination of fresh blood has been well explained and its importance demonstrated by Hayem in his valuable work, "Le Sang," the perusal of which I earnestly recommend to all those who propose to make systematic blood examinations for any purpose. Blood is so sensitive to the action of any foreign substance that the glasses used should be freed as far as possible from all extraneous matters. Slides and cover-glasses should be rinsed in mineral acids to remove fatty matters, and then in alcohol, or, better, a mixture of alcohol and ether, and not touched with the fingers afterwards. It is convenient to keep them in a bottle of alcohol until required. Only the thinnest cover-glasses should be used. Neither slides nor cover-glasses are perfectly flat, and it is therefore desirable in order to obtain a thin, even layer of blood that the cover-glass should be very fine, the thin glass yielding better than the thicker. It is necessary in order to prevent the formation of rouleaux to make the preparation as quickly as possible after the drop of blood exudes through the epidermis, and it is desirable to have the blood uninfluenced by moisture. To secure these objects the following hints should be attended to: 1. Spring forceps are very convenient for the preparation of dried specimens. The clean, dry cover-glass is grasped with these forceps, which are placed on a table on the left hand. 2. The finger to be pricked should be washed with soap and warm water, well dried, and then dipped in alcohol, which should be wiped off with a clean cotton or linen rag. The patient should be placed slightly to the left of the operator, an elastic band being passed (not too tightly) round a finger of the left hand at the last joint. The swollen bulb is then pricked with a sharp-edged needle, and the assistant (or patient himself) with his right hand wipes off the first drop of blood with a dry linen cloth. 3. The operator, who has a cover-glass held in forceps in his right hand, squeezes the bulb of the finger gently and catches the small drop of blood in the centre of the glass the instant it exudes, and immediately lays it diagonally on the cover-glass which is held by the spring forceps. As soon as the blood has spread out into a uniform layer between the glasses the upper cover-glass is withdrawn from the under one and both are allowed to dry. This is better done with forceps, so that the fingers may not come near the blood; but it is not always easy to withdraw the upper cover-glass with the forceps without breaking it, and the unpractised operator will often be obliged to use the thumb and forefinger for the purpose, which in most cases will not interfere with the preparations being sufficiently useful. The size of the drop of blood is of some importance, particularly in preparations examined fresh; if it is large the corpuscles are massed together; if it is too small it does

[1] Translated by the Sydenham Society.

Digitized by Google

not spread out sufficiently. Anæmic blood, as would be expected, spreads out more quickly than thick, rich blood. The right size of the drop of blood can be only learned by experience, but it will be found to be a very little larger than the head of a pin. If the preparation has been well made the red corpuscles will be found separate from each other, with sufficient space between each to admit of easy observation. Very often one part of the preparation will be useless, while the other part is good. For fresh preparations the charged cover-glass is laid immediately on the clean slide, and several should be made. Before taking a second drop of blood the bulb of the finger, which has been moistened by the previous drop, should be thoroughly dried with the linen cloth. The bulb is then again squeezed and the drop of blood taken as before. To prevent alteration of the blood by evaporation it is well to seal up each preparation as soon as it is made, which is easily done by brushing round the edges lightly with melted paraffin of a high melting-point. A small piece is melted over a spirit-lamp, and a fine camel's hair brush, after being dipped in it, is quickly drawn round the edge of the cover-glass, care being taken that the paraffin overlaps both the glasses. It dries almost immediately and the preparation is available for examination for hours afterwards. In examining fresh blood for the parasite the points to be looked for in the red corpuscles are alteration in size and defined clear spaces of various shapes with or without pigment. In the corpuscles the presence of pigment in these spaces is indicated either by very minute separate particles or by small rod shapes or by clumps, and the movements seen in the earlier stages of the parasite are indicated by the rapid changes in form of the clear outlines. In the mature parasite, in which spore formation is taking place, the corpuscle is found to be filled with a round colourless body dividing into spores, with the pigment at the periphery or in a block in the centre, or passing in lines towards the centre. In the stage between that of the small, round, clear parasite which has recently attacked the corpuscle and the fully developed stage in which spore formation begins to take place, minute grains of pigment are found in active motion. This appearance is very characteristic and cannot fail to catch the eye even of the inexperienced observer. The pigment is coarser in the quartan than in the tertian parasite, slightly lighter in colour, and with much more sluggish movement. The coarser pigment, the small number of spores—usually about eight—and their larger size, and the fact that the affected corpuscle does not increase in size are the distinctive features of the quartan as compared with the tertian parasite, the increase of size of the red corpuscle, its rapid discolouration, and the swiftly moving pigment being the chief appearances to be noted in corpuscles which harbour the latter. If it is a case of tertian or quartan with which the observer has to do he will not have much difficulty in detecting the parasite, more particularly if he examines about eight or ten hours before the attack. In cases of double tertian he will find it still more easy on account of the different stages of development which he will observe at the same time. But if he has to do with a case of the more malignant forms of malaria, or the chronic irregular tropical fevers, he may have great difficulty in observing the parasite, which in these cases is very often found only at long intervals in the blood from the finger, and then only for the short time that it is in the condition of the small, round, colourless amœba, without pigment and either in motion or motionless; or, in addition to this colourless state, the parasite may be indicated by the presence of small clear spaces in the corpuscles containing minute rod- or comma-shaped pigment forms or surrounded by a very small amount of pigment in fine grains. In these cases he will not observe the large parasite filling up a considerable portion of the corpuscle or dividing into segments. In this class of patients the diagnosis is rendered much easier by the observation of two appearances of a different kind. The crescent form, lasting over a longer or a shorter period, is usually found in these fevers if persistently looked for and can be easily recognised. Also, during a period not well defined for these fevers, white corpuscles may be found containing rounded or irregularly shaped blocks of pigment. Both these appearances are characteristic.

It is in the examination of fresh blood that high-power objectives of fine quality are more especially necessary. The small colourless parasite may be easily confounded with vacuoles in the red corpuscle, and their detection requires the combination of a certain amount of experience and good optical apparatus.

4. *The use of dyes in preparations of malarial blood.*—The use of stained dried blood preparations is not only valuable for confirmation of inferences drawn from the appearances seen in the fresh blood, but possesses special additional advantages, which render it, in my opinion, indispensable. I will therefore describe what I have found in my own experience to be the most satisfactory methods of staining the parasite, after having tried most of the methods recommended in Mannaberg's monograph and many of the dyes and staining processes described in Lee's useful work, "The Microtomist's Vade-Mecum," a book I cannot too highly recommend to those who are engaged in any kind of microscopical work in which the use of dyes plays a prominent part. To save space I shall only notice the methods which, so far, I have myself found most useful.

The cover-glasses which are destined for staining, after being prepared as I have already described, may be placed with advantage in absolute alcohol for three minutes before the blood has become quite dry, although this is not quite necessary. When dry they are wrapped in soft paper and put aside for subsequent use. The most convenient dye is the well-known combination of eosin and methylene blue, but it is far from being a matter of indifference how these dyes are used. Eosin is an acid and methylene blue a basic colour, and when used successively one may destroy the other unless the exact time and strength are hit. For this reason I found that using the dyes one after the other was very troublesome, and not so serviceable as the use of methylene blue alone—as, for example, Löffler's alkaline solution;[2] but the eosin has the advantage not only of being a contrast to the blue, but, from its property of staining hæmoglobin, it facilitates the distinction of a red corpuscle containing a round-shaped parasite from the small mono-nuclear white corpuscles. It is well, therefore, to use a mixture of the two dyes in proper proportions. After trying various formulæ I have found Chezynsky's the best for general purposes, which is made by mixing "half per cent. solution of eosin in 70 per cent. alcohol, 20 parts; concentrated solution of methylene blue in distilled water, 40 parts; water, 40 parts."[3] In preparing this mixture I think the precise strength of the alcohol is of importance.[4] For "concentrated" solution of methylene blue it would be more precise to write "saturated" solution. I have found the results most satisfactory by taking care that the solution of blue was really saturated. Some of this solution is filtered into a watch-glass, and the cover-glass with the blood surface downwards is floated on the fluid. The length of time which should be allowed for the staining is, I think, generally understated, and depends on the temperature. I generally use an incubator at a temperature of about 98° F., and at this heat a quarter of an hour to about twenty minutes amply suffices; at room temperature half an hour to two hours may be found necessary, according to the time of the year. If the preparation is an important one it is advisable to watch the staining process by washing off the dye occasionally with distilled water and looking at it unmounted with a low power, putting it back in the dye if necessary, until the requisite degree of staining is obtained. When this has been found the cover-glass is washed in distilled water and allowed to thoroughly dry, and is then mounted as a dried preparation, being kept in position on the slide by a margin of melted paraffin brushed round it in the manner I have described for fresh blood. It may be examined at once or after a period of weeks. After a little practice the parasites can be easily picked out in such preparations with a very low power. For this purpose I use successfully a low-power objective with Powell and Lealand's No. 10 compensating eye-piece. This gives me a very large, clear field, the magnifying power being 210 diameters, and the blue-stained parasite stands out distinctly and boldly (although a very minute object) in the red corpuscle. When a parasite has been found it may be examined by a high-power objective, an $\frac{1}{8}$th or higher, when the pigment, if present, should be seen more or less distinctly according to its fineness and distribution; but

[2] Thirty cubic centimetres of saturated solution of methylene blue in alcohol: 100 cubic centimetre solution of potash of strength 1 in 10,000.

[3] It is very important that aniline dyes should be pure. Dr. Gruebler of Leipzig supplies them in a reliable condition for histological purposes, and Dr. Ranthack, 21, Golden-square, London, W., acts as agent for the supply in England and will forward any of the dyes or solutions referred to in this paper.

[4] Seventy per cent. alcohol is made from methylated alcohol, which must be free from naphtha, by diluting 100 measures to 121; from absolute alcohol (0·793) by adding 34¼ volumes of water to 100 volumes of the alcohol. In working with aniline dyes it is best to avoid the use of methylated alcohol.

Digitized by Google

for satisfactory examination, particularly as regards the stage of development of the parasite and the distribution of the pigment granules, an oil immersion objective should be used.

For the size and form of the parasite and its relations to the red corpuscle, and for the presence and condition of the pigment, the use of methylene blue and eosin is sufficient. Eosin is particularly useful in showing the poverty in hæmoglobin of the large, swollen red corpuscle which harbours the tertian parasite. In order to render the detection of the parasite by this method easier to those who are beginning the work I have thought it useful to show by definite outlines, drawn to scale, the size of the objects which have to be looked for, according to the magnifying power which is used. Although I recommend every observer to provide himself with apparatus which will give him a magnification of 1000 diameters, it must happen to many to be obliged to use a lower power, at all events for a time. I have therefore made the drawings which are printed in the accompanying plate chiefly to two scales, one of 500 and one of 1000 diameters; 500 diameters being within the reach of most—even of the commoner—microscopes, if the highest system with which they are provided is of sufficient quality to bear a fairly high eye-piece. For the finer details of the structure of the parasite, more particularly of the spores, hæmatoxylin should be employed. It is by the use of this dye that Mannaberg has made a distinct advance in our knowledge of this difficult subject. The process which he recommends, although apparently somewhat complicated, is not difficult to carry out. "The dried preparation is floated for five minutes in distilled water, and after being dried with blotting-paper is passed several times through a weak solution of acetic acid (a drop of acetic acid in twenty centimetres of distilled water) until the hæmoglobin disappears. The colourless preparation is then laid for two hours in the following fixing fluid: concentrated aqueous solution of picric acid 30, distilled water 30, glacial acetic acid 1. From this mixture it is placed for another two hours in absolute alcohol, and then placed from twelve to twenty-four hours in an alum hæmatoxylin solution. Differentiation of the stain is effected by using a quarter per cent. hydrochloric acid alcohol (alcohol of 75 per cent.) and then ammoniated alcohol (3 drops of ammonia in 10 cubic centimetres of 75 per cent. alcohol), which is washed out in 80 per cent. alcohol. The preparation is mounted in Canada balsam dissolved in xylol." The process is a tedious one, and care must be taken regarding the strength of the hydrochloric acid alcohol. If the ammonia is used too strong, or for too long a period, it acts very destructively. Unless the preparation is allowed to dry thoroughly before mounting in balsam I recommend a stronger—say, absolute—alcohol. Some of the most interesting appearances shown in Mannaberg's book, such as those in the Plates III. and IV., were obtained by this process, and these drawings cannot be neglected by anyone who studies the structure and development of the parasite. I have made some experiments with the view of ascertaining whether we cannot get similar results by a simpler method. These are not quite finished, but so far as they have gone they show that the selective action of hæmatoxylin on the chromatin of the spores can be obtained by a shorter procedure. It had been known for some time that appearances indicative of nuclear structure could be observed, particularly in the large spores of the quartan parasite, and Mannaberg has shown by his methods that nuclear structures can be clearly stained in the spores of the tertian parasite. I have found that the same appearances as those described by Mannaberg can be demonstrated by the simple use of hæmatoxylin, and, as I shall subsequently show, the same structural appearance can be brought out in the parasite of perniciosa comatosa by an analogous method. For this purpose I recommend the use of Mayer's hæmalum instead of the ordinary hæmatoxylin solutions, according to the formula given in Lee's Vade-Mecum. One gramme of hæmatein dissolved by heat in 50 cubic centimetres of 90 per cent. alcohol is added to a solution of 50 grammes of alum dissolved in a litre of distilled water. The mixture is allowed to cool and settle, filtered if necessary, and a crystal of thymol is added to preserve from mould. The preparations are placed in this dye until sufficient staining is produced, or, which I think is better, until the preparation is considerably over-stained, the excess of colour being then removed with a half per cent. solution of alum. After washing with water the preparation should be further placed for a few seconds or a minute (it is easily overdone) in a weak solution of eosin, in order to stain the hæmoglobin of the red corpuscle. If the eosin is used sufficiently diluted the desired tint can be obtained without excess of colouring, and the hæmalum stain is not obscured, the result, I think, presenting some advantages over the absolute decolouration by Mannaberg's method. As the object in this mode of preparation is to bring out the extremely small nuclear elements it is obvious that it is useless except when very high magnifying powers are used. In preparations stained in this way, and examined by Powell and Lealand's apochromatic $\frac{1}{12}$th oil immersion (numerical aperture, 1·40), with No. 10 compensating eye-piece, the chromatin elements described by Mannaberg as nucleolus and the surrounding protoplasm of the spore can be distinctly seen. In order to obtain sufficient enlargement to make these points clear in the Plate I have made some camera lucida drawings of the tertian sporulating parasite with Powell and Lealand's apochromatic $\frac{1}{50}$th (numerical aperture 1 40), with the No. 10 eye-piece, which gives a magnification of 2000 diameters, whilst retaining sufficiently good definition to enable the details of the preparation to be clearly seen. A more easily managed contrast stain than eosin, which I have so far used more in sections, but which deserves to be more tried in preparations of the kind with which I am now dealing, is Mayer's cochineal, which, like eosin, stains the hæmoglobin of the red corpuscle. Eosin, when used a little too strongly, stains also the protoplasm of the white corpuscle, and the difference between the red and the white corpuscle is then less marked than when cochineal is used. This dye leaves the protoplasm of the white corpuscle unaffected, and it is useful in some cases to be able to distinguish easily and with certainty in stained preparations the red corpuscle from the small mononuclear or the lymphoid white corpuscle. The presence of pigment in the white corpuscle is valuable as a diagnostic mark, and can be well studied in blood preparations and sections stained with eosin and methylene blue. The drawings (Fig. 13, *a*, *b*, *c*, and *d*) show the form and size which it frequently assumes.

5. *The staining and studying of sections*.—The staining of sections of malarial tissues is very useful, as it is from this line of research that we must look for information regarding the life history of the parasite (from the clinical point of view very important) which produces the deadly fevers occurring mostly in the tropics, and which have given to malaria its most terrible significance. Golgi in his letter to Baccelli (p. 44) refers to a case in which during life blood from the finger gave constant negative results, whilst blood from the spleen showed a great number of parasites in different phases of development. So far as he could judge from the examination of the specimens (incomplete at the time he wrote), the affection was localised exclusively in the spleen. He refers to another case, in which a surprising localisation of the malaria parasite in all its phases of development was found in the intestine, whilst in the other organs the number was either very few or there were none at all. Similar specimens were shown by Marchiafava at the Congress at Rome. Golgi suggests the question whether the parasites which are found in these malignant fevers in the medullary or splenic cells, instead of undergoing a process of phagocytosis, are not undergoing in these cells a process of development, accomplishing there a true endocellular cycle. It is clear, then, how important it is that the post-mortem tissues should be examined under the best possible conditions. This is a part of the subject to which I can contribute very little, my experience being limited to a prolonged series of experiments in staining, made on sections of the brain and spleen prepared from tissues from cases of perniciosa given to me by Professor Marchiafava and Dr. Bignami when I was at Rome last year. As Dr. Bignami has had a large experience in the examining of malarial tissues, I quote from his "Ricerche sull' Anatomia Patologica delle Perniciose" (Estratto dagli Atti della Accademia Medica di Roma, anno xvi., vol. v., serie ii.). "In the greater number of cases tissues have been fixed in absolute alcohol, some in the liquid of Kleinenberg, some in perchloride of mercury. The best methods are fixation in absolute alcohol, and fixation in 1 per cent. solution of perchloride of mercury in distilled water, to which $\frac{3}{4}$ per cent. sodium chloride and from $\frac{1}{2}$ to 1 per cent. acetic acid are added. This fluid combines the conditions of Carnoy's and Deny's liquids. It penetrates easily into tissues, fixes them rapidly, preserves the red corpuscles without removing the hæmoglobin, a distinct advantage in studying the endoglobular parasite. In this solution, which I have found

Digitized by Google

more especially useful in studying the spleen and the medulla of the bones, the portions of the tissue remain for a quarter of an hour to an hour, or several hours, according to size, and are then passed through iodised alcohol, and finally to absolute alcohol." I would suggest that the portions hardened should be small in size, say not larger than half an inch cube, and those which are to be kept some time should, when sufficiently hardened in absolute alcohol, be preserved in 70 per cent. alcohol. The brain, the spleen, and the liver are best cut by the paraffin process, the success of which depends on a number of details which are very well explained in Lee's book. After trying a great many methods of staining by aniline and other dyes, I have come to the conclusion that for the demonstration of the parasite nothing is better than the various solutions of methylene blue, with or without eosin. Some of the substitution methods which are described in Lee's book are useful in showing the composite character of the chromatin elements in the early stage of the parasite and I would specially recommend that by vesuvin and gentian violet for this purpose. For the study of the nuclear structures, however, I have found hæmalum better than any of the other dyes I have tried, and the best results I have got were obtained by double staining in hæmalum and cochineal. The method which was most successful consisted in long staining with hæmalum, a day or even longer, and washing out the excess of colour by soaking in ½ per cent. solution of alum; the section is then washed in water and stained slowly in cochineal. The cochineal as a contrast stain has been for this purpose, in my hands, better than eosin, being less intense and more selective. The tissues with which I experimented had been kept for a considerable time in alcohol, and sections of the brain and spleen with many dyes did not show a trace of the red corpuscles, the parasites being represented in the apparently empty capillaries by very minute, round, stained bodies, which Mannaberg would call the nucleolus, and which can be seen by a good objective to be composed of minute, round, separate points of chromatin. In similar sections treated by cochineal the contours of the red blood-corpuscles were well marked, and the more deeply stained parasite could be seen within the corpuscles. (See Fig. 3.) In very successfully stained preparations of the brain the parasite, which, in the tissue examined by me, was still in an early stage of development, could be seen to be composed always of two and sometimes distinctly of three parts, the chromatin made up of fine points very darkly stained by the hæmalum, the protoplasma mantle slightly stained, and occasionally between the nucleolar chromatin and the protoplasma mantle a small unstained space, the appearance being similar to that figured by Mannaberg in the spores of the tertian parasite. The advantages of this method of staining consist in bringing out successfully these separate elements. In the various illustrations which I have seen of the parasite of pernicious malaria, as observed in the capillaries of the brain, I have not noticed these three elements figured, and although analogy would lead us to expect to find them, it is satisfactory to be able to bring them under direct observation. They can be very clearly observed by Powell and Lealand's apochromatic $\frac{1}{12}$th, but from the small size of the bodies I have thought it better to draw them as seen when very highly magnified. The drawing in the plate (Fig. 3) to the scale of 2000 diameters was made by using Powell and Lealand's apochromatic $\frac{1}{12}$th oil immersion with the No. 10 eyepiece. The size of the red corpuscles in the drawing, compared with that shown in Fig. 1, *a*, will give an idea of the shrinking which had taken place from the action of the alcohol, but it does not follow that the parasite had shrunk in an equal degree with the corpuscular substance. The fullest representation of the parasite of malignant malaria (pernicious comatosa) with which I am acquainted is given in one of the plates in Bignami's paper already referred to, "Ricerche sull' Anatomia," &c. Both the pigmented and the unpigmented parasite of pernicious quotidian, as seen in the bloodvessels of the brain, are copiously illustrated in these plates, all the stages of development being represented.

Cases of chronic malaria in which the crescent form of the parasite is found often present a difficulty caused by the small number of parasites which can be observed in blood taken from the finger. A person in whom there is no history of febrile symptoms for several weeks, who possibly considers himself well and free from fever, betrays by the pale lips, creamy conjunctiva, and general bloodless expression the probable existence of chronic malarial poisoning. Examination of blood from the finger will probably show no endoglobular parasites, and no pigment-bearing white corpuscles may be observed. If a crescent parasite is seen the diagnosis is easy, but a short examination may show no crescents, and the long, repeated examinations which are necessary to settle the point may become extremely irksome to a man actively engaged in practice. It occurred to me, therefore, to try some method by which large drops of blood could be examined, so as to greatly multiply the chances of detecting crescents, and after a considerable experience I can recommend the following procedure. If a small drop of filtered saturated solution of methyl green, to which 1 per cent. of acetic acid has been added, is placed on the slide, and the cover-glass with the freshly drawn blood is placed over it, the drop of methyl green solution mixes rapidly with the drop of blood, and after sealing with paraffin the preparation is ready for examination. What has happened is this—the hæmoglobin is no longer visible, and the decolourised red corpuscles, being only detected by their fine contours, no longer impede observation, and if any crescents are present they can be readily picked out by a low power. The white corpuscles are seen as round bodies bounded by a thin line, their protoplasm is almost colourless, and their nuclei are stained pale green. The crescents when present are easily detected by the central accumulation of pigment, the body of the parasite being seen as a smooth, cleanly contoured body of a pale green colour. (See Fig. 5, *a*, *b*.) Some of the crescents appear to undergo very little change in this solution, others appear to be considerably shrunk, the more stable portion of the parasite being that which is next to the central pigment. I have added a weak chromic acid solution to this mixture, and I have also mixed it, with and without weak chromic acid solution, with glycerine without notably modifying the results. I have found, in a preparation in which glycerine had been mixed with the solution, that the crescents lost nothing in their definition and colour for some months. After eleven months the contour and definition were well marked, but the colour was much faded. This method, then, is useful for permanent preparations, but, as paraffin is apt to crack, it is well to brush Bell's cement over it if they are to be kept. The ordinary forms of endoglobular parasite can also be observed by this method, but so far I have used it chiefly, and most successfully, in searching for crescents.

6. *Remarks on the clinical aspect of the question.*—The utility of examining blood for the malaria parasite in cases of fever is too evident to be enlarged upon, but its utility is much greater in some classes of cases than in others. It does not require a microscope to diagnose or treat successfully a case of classical ague, or even many of the cases of irregular and remittent fevers which are due to malaria, although microscopic observation is much more important in them than in tertian and quartan fevers. It is certain, however, that even in malarial countries many cases of fever are diagnosed and treated by skilled and experienced observers as of a malarial nature which are really due to other causes. There are cases in which a considerable time must elapse before the diagnosis can be made from the clinical symptoms alone. I conceive that it is very important to use the microscope in cases of so-called "fever from exposure to the sun," and I am afraid that occasionally cases diagnosed and treated as sunstroke are examples of pernicious malaria with coma. In all doubtful cases of fever, therefore, occurring in countries where, for example, the diagnosis may lie between typhoid fever and malaria and "sun fever," the microscope should be used, and it should also be employed for diagnostic purposes in many cases of coma with acute febrile symptoms which might perhaps more naturally suggest sunstroke. Very important is it to use the microscope in cases of a different class. Persons who have suffered from malarial fevers in the tropics and who have returned to England frequently suffer from what they believe to be malarial attacks, for which they take quinine, often in large and unmeasured doses. On simply clinical evidence, and long before I knew anything of the malaria parasite, I had satisfied myself that the great majority of these cases were not cases of malarial fever at all, and that the use of quinine was injurious. In many of these patients there is a slight daily rise in temperature, but in others it remains subnormal, notwithstanding that the symptoms of malaise, weariness, and aching pains in the bones are very similar to the symptoms with which they were familiar as accompanying the true attacks of malarial fever

Digitized by Google

which they had in the tropics. Hence nothing can be more natural than that they should imagine that they have the same fever, and, if there is a slight rise in the temperature, it is equally natural that the medical attendant should be of the same opinion. By the use of the microscope I have satisfied myself that my belief as to the non-malarial nature of these cases was correct. Shortly after I began these investigations a young man was sent to me by a physician long experienced in tropical diseases as a subject well fitted to afford material for the study of the parasite. His bloodless look and shattered appearance gave me the same impression, and it was with some surprise that I found no trace of the parasite in his blood. Not content with one or two fruitless examinations, I spent a considerable time in examining his blood daily for a week, but always with a negative result. Looking back on the case now, I recognise that what this young man suffered from was not the malarial parasite in his blood, but the damage done to the viscera before he left India by the parasite which he then harboured. Quinine is of course useless in such cases. Quite recently a former patient, an anæmic, feeble man, was affected whilst in the country by chill. There was a daily rise in temperature, malarial fever was diagnosed, and he was treated by large doses of quinine. His condition did not improve, and when I saw him in London some weeks afterwards an examination of the blood, both before and after the slight daily rise in temperature, afforded no evidence of malarial disease. These are only examples of other cases of a like nature. My observations on the cause of the symptoms in this class of cases are yet so incomplete that I hesitate to use them in suggesting an explanation of the symptoms, but I hazard the theory that in most of them the discomfort, debility, and febrile accesses are associated with the damage sustained by the blood-forming organs when the patients suffered from malaria in the tropics. The destructive action of the malarial parasite on the tissues of the spleen, the liver, and the bone marrow have been well worked out and described, particularly by Bignami, and there is no doubt that in a certain proportion of these cases this damage is never thoroughly repaired.

Whether these people are well or ill, I find they are more or less anæmic, the change in the number and condition of the corpuscular elements of the blood being sometimes very marked. When they get chilled or suffer from continuous cold weather, or undergo much fatigue or experience depressing mental emotions, they become affected with many of the symptoms which are associated with the febrile state, and there is often a rise of one to two degrees of temperature. Quinine does them no good, but if they remain in bed for two or three days, and take an appropriate diet, the symptoms usually soon disappear. It is the frequent recurrence of these symptoms that has led to the idea that persons who have had malarial fever remain always liable to fresh attacks, even after they have returned to temperate climates. I am satisfied that not only is this not the case, but that a great proportion of the persons who have suffered from malarial fever in the tropics, particularly those who are not aged and are naturally robust, recover perfectly within a comparatively short time. I am familiar with many instances of men who have been sent home on account of fever and have recovered entirely before reaching England, and have never had another attack. To assume that all persons who have once had malarial fever are liable to it in the future is an assumption that is not based on evidence. On the other hand, we see in London two classes of true malarial fever. There are cases in which the patient may have recovered to some extent on the voyage home, but is seized shortly after his arrival in England with well-marked and often severe symptoms of fever, in which the nature of the disease is manifested both by the high temperature and the detection of the parasite in the blood. These cases, it is needless to remark, are more or less amenable to quinine, according to the dose and the manner in which it is administered, and as very large doses of quinine are sometimes required it is important to be fortified in the diagnosis by the detection of the parasite. Looking back on the pre-parasite days I can recollect the anxiety with which I recommended thirty grains of quinine daily for a small delicate woman dangerously ill from severe malarial fever which she had contracted in the south of Spain; twenty grains of quinine a day had been given by the medical man with whom I saw her without effect. Her condition being critical, I advised that the dose should be increased to thirty grains daily, with the result that there was a speedy fall in the temperature and a final cure. I can recall a similar case in a man from Mexico, who although not dangerously was seriously ill, and in whom the fever, which did not yield to the doses usually given in malarial fever, also yielded satisfactorily to a larger dose. The microscope is now a great stand-by in dealing with such cases, by giving much needed confidence when unusually large doses are indicated. Another class of case which we see in London is of a very different kind. The patient either has no febrile symptoms, or has them at such long intervals that he may possibly not suspect that he has fever at all. Last summer I was consulted by an officer who had contracted fever when on a shooting expedition in the jungle in India. He treated himself with quinine, and after a week the acute symptoms disappeared and he considered that his fever was cured. He had nothing to complain of except that he was supposed to have had a deranged liver for some days on his way home, but his listless manner and marked anæmic appearance impressed his relatives so strongly that they recommended him to consult me. Microscopic examination showed at once the presence of a fair number of crescents in his blood. I sent him to Scotland, where, about three weeks afterwards, he had a distinct febrile attack which I have no doubt was malarial; but under the judicious use of arsenic and iron and moderate doses of quinine he recovered a healthy appearance, and two months later one long examination failed to show any malaria parasites in his blood. As he remained in good health he shortly afterwards returned to India. Two other cases may be briefly quoted as types of the cases in which the crescent form is found. A young man who had acquired fever in Bombay, the attacks being characterised by much nausea and vomiting, had not had for a considerable time any active febrile symptoms or rise of temperature, but his extreme pallor and great weakness were strongly indicative of the slow destructive effect of some noxious agent upon the blood. Continuous diarrhœa, which had lasted for weeks, yielded at once to exclusive milk diet. Crescents were found for about a fortnight, and although I examined his blood every two or three days during that time I only once found another form of the parasite. He was liable once in two or three weeks to attacks of fever, the chief symptom being frequent retching, with great debility and malaise, lasting for two days. After one of these attacks I found on one occasion a considerable number of small colourless amœbæ attached to the surface of the red corpuscles, some of them simply round, some of them ring-shaped—a form of parasite which can only be recognised with certainty by the use of high powers and a good objective, and which might easily be confused with the vacuoles in the red corpuscles. I refer to another case chiefly with the object of indicating the treatment under which the patient recovered. This man had acquired fever in India some six months previously, the disease being attended at the outset with severe continuous febrile symptoms and great nausea and vomiting. After about a week his febrile symptoms abated, but he had never been quite well since the beginning of the attack, and every twelve days he was prostrated with symptoms of fever, always accompanied with severe vomiting. I examined the blood three times at intervals of five or six days when no fever was present, and each time found crescents but no other form of parasite. He had taken much quinine during the six months his illness had lasted, and, as it was possible to calculate with some certainty the time that the fever would recur, I recommended him to take twenty grains of quinine daily in two ten-grain doses for two days before the next attack. This did not prevent the expected attack, but I directed him to repeat the same dose in the same way two days before the next expected period of recurrence. This time the attack did not appear, and he entirely regained his health. It is difficult to be sure which of these doses of quinine cured him, but, judging by analogy from Golgi's observations on the action of quinine on the malarial parasite, it is probable that, although the first series of doses did not prevent the attack, the brood of young amœbæ succumbed to the effects of the quinine which was in the blood when they were set free. The favourable action of the quinine was probably assisted by the return of the patient to the climate of England.

The slight sketch which I have given of these few illustrative cases will suffice to indicate the improved position we now occupy in treating cases of malarial fever in the light

TO ILLUSTRATE DR THIN'S ARTICLE ON THE

MALARIA PARASITE.

Digitized by Google

afforded by microscopical examination of the blood. Unfortunately the technical skill needed for this examination can only be acquired by serious application to a study which has many difficulties and pitfalls. These can, however, be overcome by any medical man living in a malarial country who will give sufficient time to the subject and will provide himself with the necessary apparatus. I hope the hints that I have given in this paper, which are based on my own experience, may prove useful to workers who are absent from great centres and by whom all technical work must be carried on at a disadvantage. It is my pleasant duty to record my obligation to my friend Dr. Marshall of Rio Tinto, who has been a zealous coadjutor in this study for more than a year, and who has furnished me with much valuable material.

EXPLANATION OF THE PLATE.

Fig. 1.—A red blood-corpuscle from fresh normal blood, drawn to scale by camera lucida, to form a standard for comparison with the figures of dried and stained blood which follow. (The colour of the fresh blood is not reproduced.) *a* × 500 diameters; *b*, × 1000 diameters; and *c*, × 2000 diameters. (In this and the subsequent figures the objectives employed were, for the 500 diameters, a dry objective by Powell and Lealand; for the 1000 diameters Powell and Lealand's apochromatic $\frac{1}{12}$th oil immersion with the No. 10 eye-piece, or the $\frac{1}{16}$th apochromatic oil immersion of the same makers with a low eye-piece; for the 2000 diameters the $\frac{1}{16}$th with No. 10 eye-piece.)

Fig. 2.—Blood from a dried preparation stained in hæmatoxylin and mounted in glycerine; chronic irregular fever; sporulation in internal organs. The blood, which is from the finger, shows the red corpuscles being attacked by the parasite in its earliest stage. In one corpuscle two parasites are observed. The part chosen for drawing contained an unusual number of affected corpuscles. *a*, × 500 diameters; and *b*, × 1000 diameters.

Fig. 3.—A bloodvessel from a section of a portion of brain given to me by Dr. Bignami from Professor Marchiafava's laboratory in Rome. The section, which was cut in paraffin, was stained in hæmalum and cochineal. *a*. a red corpuscle containing no parasite; *b*. a red corpuscle containing an eccentrically situated parasite; *c*. a red corpuscle containing two parasites. The protoplasm of the parasite is stained a deep pink, the nuclear elements a very dark purple. (In this and similar preparations the resolution of the stained nuclear elements into separate minute spheres depends to a considerable extent on the excellence of the objective used). The darkly stained nuclear elements of the parasite as shown in this figure must not be confounded with pigment. No pigment was observed in the section, and the case was therefore probably one of quotidiana perniciosa caused by the pigmentless quotidian parasite described by Marchiafava and Bignami.

Fig. 4.—The crescent-shaped form of the parasite found in the blood in irregular chronic fever. The dried blood from the finger was stained by hæmalum in excess, and subsequently partially decolourised by weak hydrochloric acid. (See Mannaberg's process, as described in the text). *a*. The parasite with arc-shaped line indicating the contour of the red corpuscle in which it had developed. *b*. Free parasite × 500 diameters. *c* and *d*. The same × 1000 diameters. *e*. Red corpuscles in the same preparation × 1000 diameters.

Fig. 5.—Crescent-shaped parasites in the blood, sealed in solution of methyl green in 1 per cent. acetic acid. The colour of the methyl green is not shown in the plate. *a*. A crescent sealed in the solution, to which a little glycerine has been added. *b*. A crescent in the solution without glycerine, drawn shortly after being sealed. Many crescents seen in this staining solution have the shortened, mutilated appearance shown by this one. The red corpuscles, which are much shrunk in size, are quite colourless, and are indicated only by very fine lines, much fainter than is shown in the drawing. The magnification in this figure was not accurately estimated, but that of *a* is about 700 to 800 diameters, and that of *b* nearly 1000. The red corpuscles in *b* had shrunk more than those in *a*. *c*. A red corpuscle containing a round parasite with peripheral pigment from a case of irregular fever with the formation of crescent bodies. Sporulating forms were not found in blood from the finger. This drawing is shown under this figure because it is typical of forms that are found (in my experience, sparingly) in cases with crescent formation. The drawing was not to scale by camera lucida, but the magnification is slightly over 1000 diameters; eosin and methylene blue.

Fig. 6.—A red corpuscle containing the tertian parasite before the formation of pigment; eosin and methylene blue; the parasite is stained blue. × 1000 diameters.

Fig. 7.—A red corpuscle containing the tertian parasite with the beginning of pigment formation and two normal red corpuscles beside it; eosin and methylene blue. The larger size of the corpuscle which contains the parasite is to be noted. × 1000 diameters.

Fig. 8.—A red corpuscle containing the parasite in a more advanced stage of pigment formation. Note the serrated appearance at one part of what remains of the red corpuscle, caused by the destructive action of the parasite. × 1000 diameters; eosin and methylene blue.

Fig. 9.—The tertian parasite with spore formation and central pigment. The number of spores is unusually small for the tertian parasite. Note the disappearance of the hæmoglobin from the red corpuscle and its comparatively large size as compared with the normal corpuscles around it, which appear to have been considerably shrunk by the drying process. × 1000 diameters; eosin and methylene blue.

Fig. 10.—*a*. A red corpuscle containing the tertian parasite with spore formation complete; hæmalum and eosin. The nuclear element of each spore is stained by the hæmalum. × 1000 diameters. *b*. The same × 2000 diameters. Note the contour of the perfectly colourless red corpuscle, and that in the parasite between the spore zone and the mass of central pigment there is a structureless substance less deeply stained than the spores.

Fig. 11.—The tertian parasite. A group of spores just separated from the corpuscle; hæmalum and eosin. The position of the central mass of pigment shows that the relative position of the spores has been comparatively little changed by drawing the one cover-glass over the other in making the preparation. Each spore contains a distinct hæmalum-stained nuclear element. *a*, × 1000 diameters; *b*, × 2000 diameters.

Fig. 12.—Sporulating form of the quartan parasite stained by alkaline (Löffler's) methylene blue. Sporulation is complete, with central pigment. *a*, × 500 diameters; *b*, × 1000 diameters; *c*, × 2000 diameters. Note in *b* and *c* that there is still a narrow rim of corpuscular substance preserved, that the spores are the usual number in this parasite (8), that the corpuscle which contains the parasite is hardly larger than the unaffected red corpuscles which surround it, and there is an absence of the zone between the spores and the pigment which is seen in the tertian parasite.

Fig. 13.—*a*. Phagocyte white corpuscle containing small pigment spheres. The patient was suffering from chronic malaria, acquired in Bombay. He was weak and anæmic, his spleen was slightly enlarged, and at considerable intervals he had slight fever, lasting for a day at a time. I found no parasite in the blood from the finger, but several pigment-bearing white corpuscles. The figure was drawn by camera lucida from a sealed preparation of fresh blood the day after it was prepared; × 1000 diameters. *b*. White corpuscle containing rod-shaped blocks of pigment from blood preserved in Pacini's fluid, kindly sent me by Surgeon-Major Sharpe from Sierra Leone. The patient was said to be suffering from ague, and when the blood was taken his temperature was 105° F. No parasites were found in the red corpuscles, but there was an unusual number of white corpuscles heavily laden with pigment. (Not a camera lucida drawing, but magnifying power probably about 1000 diameters.) *c*. Phagocyte white corpuscle from dried preparation of blood from a case of chronic irregular fever. There were crescents in the fresh blood. The dark outline on the left, which did not take on the eosin colour so deeply as the rest of the corpuscle, contained minute spheres of pigment, and seemed to be formed by extremely minute powdery pigment, the particles of which were too small to draw, and is suggestive of a parasite, probably a crescent, enclosed in the corpuscle; eosin and methylene blue; × 1000 diameters. *d*. A white corpuscle containing pigment spheres in a bloodvessel in a malarial spleen. For the section from which it is taken I am indebted to Surgeon-Captain Duggan, who prepared it in the British Institute of Preventive Medicine; × 1000 diameters.

SOME CONSIDERATIONS ON THE CHLOROFORM QUESTION, SUGGESTED BY THE REPORTS OF THE HYDERABAD AND "THE LANCET" COMMISSIONS.

BY T. LAUDER BRUNTON, M.D., F.R.S.

[THE following paper was begun at the request of the Editors of THE LANCET, and was originally intended to be published as an introductory article to a reprint of the Report of THE LANCET Commission appointed to investigate the Subject of the Administration of Chloroform and other Anæsthetics from a Clinical Standpoint, published in THE LANCET of March 18th and 25th, April 1st, 15th, and 22nd, May 6th and 20th, and June 17th, 1893. In spite of considerable curtailment, Dr. Lauder Brunton finds that it has now grown much too long to serve the purpose for which it was originally intended, and the further shortening required to adapt it for this purpose might, he thinks, prevent neuro-paralysis as a cause of death during anæsthesia being presented with sufficient clearness to the medical public. The Editors of THE LANCET gladly avail themselves of the opportunity of publishing Dr. Lauder Brunton's views with regard to this most important question before the issue of the reprint.]

THE POSITION OF THE QUESTION.

Amid the burning questions bearing on the advancement of medical science during the last decade, so fruitful of progress in every department of the medical art, perhaps none has been the subject of so much elaborate discussion and research as the action of anæsthetics in general and of chloroform in particular. But the views held by investigators regarding the action of chloroform on the human organism are not harmonious, and in many cases present complete divergence on some most important points.

In any disputed question, if diametrically opposite views are held by large numbers of intelligent, honest, and well-informed people, we may consider that there is almost certainly some truth on both sides, but that neither side has apprehended the whole truth. In regard to anæsthetics, there is little or no dispute regarding the immense advantages which are conferred on mankind by their use. They not only lessen the pain of operations and remove the dread of them, which would otherwise keep the patient from having them performed until too late, but they also allow of time and care being bestowed upon operative procedures which could not otherwise be given, and they thus ensure an amount of success which would otherwise be impossible. But the dread of pain has of late years been replaced by a dread of the anæsthetic which would relieve it, and many people will now suffer the short, but extremely severe, pain caused by the extraction of a tooth rather than run the trivial risk of using an anæsthetic.

So long as we are ignorant of the exact causes of death during anæsthesia this dread must remain. It can only be removed by such a knowledge of the conditions which endanger a patient's life during the administration of an anæsthetic as will enable us to ensure the complete absence of risk in any individual case. For this we require a detailed consideration of the factors which produce death, and the question to be settled is, whether death during anæsthesia is due to (*a*) the operation itself, (*b*) the anæsthetic *per se*, (*c*) the mode of administration, (*d*) the condition of the patient, or a combination of two or more of these factors.

METHODS OF RESEARCH, EXPERIMENTAL AND CLINICAL.

In order to ascertain the exact dangers of anæsthetics and the best methods of averting them, many experimental researches have been made, and an immense amount of clinical evidence has been accumulated. The most extensive of all the researches hitherto made is undoubtedly that of the Hyderabad Chloroform Commission, appointed by His Highness the Nizam at the suggestion of Surgeon-Lieutenant-Colonel Lawrie, and the most important collection of clinical records is that of THE LANCET. There can be no doubt whatever that it is only through the combined study of clinical observation and experimental research that the truth can be obtained.

ADVANTAGES OF EACH METHOD.

Experimental Method.

It is quite clear that in spite of the millions of times that anæsthetics have been given to patients we are yet far from having attained this knowledge. The lives of human beings are too valuable to allow of any experiment being tried on them which will endanger them in the very least. We are thus prevented from testing on them the action of various alterations in the nature of the anæsthetic, the mode of applying it, the condition of the nervous system, the position of the body, the freedom or obstruction of the respiration, the effect of shock, and other factors which may tend to bring about a fatal result. It is here that experiments in the laboratory come in usefully, for, the lives of the lower animals being of little value as compared with those of men, we can without fear give anæsthetics under various conditions so as to ascertain the effect of each. Every medical man is obliged by his office to do the best he possibly can for every patient under his care, and although the imperfection of our knowledge may oblige him to administer anæsthetics without his being certain that no bad result will follow, yet he cannot try them on patients simply with a view to increase our general knowledge of their action; he can only do it for the purpose of doing the utmost good he can to the individual patient. The death of one of the lower animals from an anæsthetic is simply to it a painless and pleasant way of ending life, and it is the method chosen by humane people of saving their four-footed favourites from the weariness, discomfort, or pain which would attend a natural death either from disease or old age. But the death of a human being from an anæsthetic, though painless to the individual, may deprive a family of a father's support or a mother's guidance, wreck the lives of the survivors, and cause misery incalculable. In order to prevent such a catastrophe it is the bounden duty of those who have the necessary opportunity and training to make experiments on animals, and thus, in the words of His Highness the Nizam, when he explained the objects of the Hyderabad Commission to his staff, "to save men's lives." The number of experiments with anæsthetics on animals is perfectly insignificant in comparison with the number of times they have been tried on man, yet their value is comparatively great, not only because they are to be ranked with the fatal, rather than with the ordinary, cases in man, but also because the conditions under which death occurred have been voluntarily produced and carefully noted.

Clinical Method.

The number of cases observed by the bedside is immensely greater than that of experiments in the laboratory, and we must remember that every time an anæsthetic is administered to a patient the imperfection of our present knowledge compels us, much against our will, to make, to a certain extent, an experiment upon that patient. We try the anæsthetic; we hope that it will suit, and we do so with fair grounds, knowing that in the great majority of cases no bad result will ensue. But at present we are not absolutely certain, for occasionally and most unexpectedly untoward results follow, and patients die during the administration of an anæsthetic, even though they may have taken it before, and that repeatedly, without any misadventure. The knowledge that we require is such as will enable us to predict before the administration, either (*a*) that all anæsthetics will suit, or (*b*) that all anæsthetics must be abandoned, or (*c*) that a particular anæsthetic will be harmless in that particular case, while another might be dangerous or fatal, so that in every case we shall know with certainty what course to pursue, and thus prevent deaths from anæsthetics ever occurring.

"THE LANCET" INQUIRY.

There can be no doubt whatever that it is only through the combined use of clinical observation and experimental research that this desideratum can be supplied. It was with a view of rescuing from forgetfulness and of collating in a form available for purposes of study the clinical records which have been made up on this subject by a host of observers, that the Editors of THE LANCET undertook a commission of inquiry into this great subject the publication of which in separate form will represent the most complete collection of records on the subject of anæsthetics. In the introduction to the report of this Commission it is stated that the inquiry was meant to supplement the labours of the Hyderabad Chloroform Commission as far as possible. The investigation began by collecting statistics from the great hospitals

Digitized by Google

throughout the world. The newspaper accounts of mishaps were also sifted and every effort made to render the accounts accurate. Dr. Snow's records were also utilised, and those of the Registrar-General from which additional information was obtained. From all these sources light was sought. Yet up to the present neither clinical observations nor laboratory experiments have given such convincing proof of the action of anæsthetics that unanimity of opinion prevails on the subject. On the contrary, complete divergence of opinion exists in regard to some of the most important points. All that can at present be done, then, is to sum up as far as possible what we do know, and to point out as far as we can the direction in which work is still required.

CLASSIFICATION OF DEATHS.

One reason of our failure to understand clearly why deaths occur during anæsthesia is that we do not sufficiently know the causes of sudden death, apart from anæsthetics altogether. We sometimes see a man suffering from heart disease, and especially from fatty heart or aortic regurgitation, suddenly fall down dead. We are contented to say that it is failure of the heart, but we do not know the exact mechanism, nor do we know at all fully the mode in which death occurs from what we term "shock." Death from shock was a frequent occurrence before the introduction of anæsthetics, and we are sometimes apt to forget that death from shock may still occur although anæsthetics have been administered. Deaths under anæsthetics may be divided into (1) deaths *from* the anæsthetic; (2) deaths *during* the anæsthesia but not due to the anæsthetic and caused by shock from the operation, failure of a fatty heart, or any other cause which might have led to the patient's death even if no anæsthetic had been given; (3) deaths *during* anæsthesia, and due to the combined action of the anæsthetic and of the operation or some other cause. It is useless for any individual or committee to pronounce *ex cathedrâ* that any particular death belongs to the first, second, or third of these three classes. Each member of the medical profession will form his own judgment, and it is with the view of enabling him to form his judgment correctly that, in this paper, certain physiological and pathological data are included which cannot be readily obtained without easy access to a large library.

CARBONIC ACID AND ALCOHOL AS TYPICAL ANÆSTHETICS.

The most universal anæsthetic is carbonic acid. Very few people are anæsthetised and rendered insensible by the actual inhalation of carbonic acid in the shape of charcoal fumes,[1] of the gas in brewers' vats and old wells, or of the choke damp in coal mines. But its action as an anæsthetic when generated within the body and imperfectly excreted is almost universal. Very rarely indeed does it happen that the brain retains consciousness to the last, and the insensibility which precedes death is chiefly due to the anæsthetic action on the brain of carbonic acid accumulating in the blood from failure of the respiration. The oldest anæsthetic deliberately administered is alcohol, and in Solomon's description, the drunkard gives the anæsthetic action of strong drink as a reason for drinking again. "They have beaten me," he says, "and I felt it not. I will take it yet again." Alcohol is also the most convenient drug for studying the stages of anæsthesia, inasmuch as they are slowly produced, and each stage is sufficiently prolonged, to allow of its being carefully observed, while the usual stages of anæsthesia produced by ether and chloroform are much shorter and not so distinctly marked off from one another. The effects of anæsthetics are all, however, very much alike in character, with the exception that the stages differ in intensity and duration according to the anæsthetic employed. Thus the stimulant effect of laughing-gas is well marked, while it is hardly perceptible in the case of carbonic acid. The first symptoms produced by an anæsthetic, whether it be nitrous oxide, alcohol, ether, or chloroform, usually are increased circulation, dilatation of the blood-vessels, and a more rapid pulse. These are naturally accompanied by a glow over the surface and a feeling of general stimulation. Succeeding these is a stage of impaired action of the cerebral centres, usually accompanied by lessened sensibility to external impressions, which may be termed the "narcotic action." Then comes the anæsthetic action, when the individual becomes insensible to external impressions, painful or otherwise, but the respiration keeps steady and the pulse is regular and strong. Even with alcohol, however, a further stage may be reached, when the respiration will cease and the pulse also, as in cases where enormous quantities of liquor have been drunk for a wager.

[1] In charcoal fumes there is a large proportion of carbonic oxide as well as carbonic acid.

STAGES OF ANÆSTHESIA.

The action of anæsthetics may thus be divided into four stages:—

(1) The stimulant stage.
(2) The narcotic stage.
(3) The anæsthetic stage.
(4) The paralytic stage.

In the case of alcohol the stage of stimulation is much prolonged, and is capable of many subdivisions. The later part of this stage is sometimes indicated in popular language as "jolly drunk," the narcotic stage as "stupid drunk," while the term "dead drunk" is applied to the anæsthetic stage.

DEATH "FROM" AND "DURING" ALCOHOLIC INTOXICATION.

Usually recovery takes place, even from the "dead drunk" stage, though it does not always do so, and the condition may pass into the paralytic stage and death occur. The death in such a case is due to the action of the alcohol, pure and simple. It is death *from* the administration of alcohol. But in the earlier stages of intoxication death may be caused by the man falling over a precipice which he would have avoided had he been sober, or he may fall on his face in the road and be drowned in a puddle two inches deep when too drunk to know what has happened. In such cases death is no doubt due to alcohol, yet it is not caused by the action of alcohol pure and simple. It is death *during* intoxication rather than death *from* intoxication. The proximate cause of death is not the action on the nerve centres or heart of the alcohol which has been absorbed, but that of *shock* from falling in the former and that of *suffocation* by drowning in the latter case.

DEATHS "FROM" AND "DURING" ANÆSTHESIA.

What is true of alcohol is true also of other anæsthetics, and the death of patients during anæsthesia produced by chloroform or ether may be no more due to the action of the anæsthetic than the deaths of the men who were smashed or drowned in the cases just mentioned were due to alcohol. They may die from the shock of an operation, from emotion, from failure of a fatty heart, from hæmorrhage, or from suffocation. The suffocation may be caused by spasm of the glottis, plugging of the windpipe or bronchi, obstruction of the nose and mouth by position, or by pressure on the thorax or abdomen. In all such cases, death, though occurring *during* anæsthesia, ought not to be said to be *from* the anæsthetic.[2] If a murderer throttles a man who has been rendered insensible by the action of a narcotic or anæsthetic, it is absurd to ascribe the death to the anæsthetic, and the same would be true if, instead of compressing the windpipe, he choked his victim by making him breathe a strongly irritant vapour such as strong ammonia or chlorine. Nor would the case be altered if, instead of chlorine, he used chloroform containing free chlorine or other irritating substances or if he used the vapour of chloroform itself in such concentration as to prove a local irritant to the air passages. In such a case it is not the anæsthetic which is to be blamed but the mode of administration. Every now and again cases occur in which the whole blame for the patient's death is laid upon the anæsthetic because the patient died after two or three whiffs of chloroform, and before the operation had ever been begun. Instances of this may be found in Case 267. "The patient got a whiff or two of chloroform and was dead." In Case 415 the patient "had hardly taken two whiffs when the respiration ceased, and he was dead." In 420, in an operation for cancer of the tongue, the patient died before the operation was commenced. Yet such occurrences may simply be due to death from fright, from suffocation by spasm of the glottis, or still more likely to neuroparalysis, a condition which we shall presently discuss. There are cases on record where a man has died simply from a touch when he was expecting to be killed. The touch was not capable of doing him any harm, but it was the mental condition which affected him and not the touch upon his skin.

USE OF ANÆSTHETICS IN LESSENING SHOCK.

During partial anæsthesia by alcohol shock is frequently lessened to a considerable extent, and drunken men

[2] Whenever reference is made to the cases of death recorded by THE LANCET Commission, it must be remembered that the cause of death entered in the report is the one assigned by the original reporter and not by THE LANCET Commission.

Digitized by Google

will sustain falls or other injuries without any trace of the shock which would have been expected to occur had the accident happened to one who was perfectly sober. At the same time, an intoxicated man may be killed by the shock of a fall when thrown from his horse with sufficient violence, notwithstanding the lessened susceptibility to shock which the alcohol has produced. What happens in alcohol happens also in the case of other anæsthetics. How interesting a light would be cast upon the causes of deaths under chloroform if an approximation of the numbers of sudden deaths during operation previous to the introduction of chloroform could in any way be ascertained. Many deaths used to occur then. Deaths still occur during imperfect anæsthesia, and it is possible that deaths may occur from shock, even during profound anæsthesia. A consideration of the table on page 635 of the report is most instructive in this connexion as showing the nature of the operation as a factor in determining death. The table records in all 83 deaths as having taken place during the reduction of some dislocation. For extraction of teeth 53 deaths are recorded; for amputation of finger, 21; for fistula in ano, 20; for avulsion of the toe-nail, 13; for opening abscesses, 14; for catheterisation, 8; and extracting thorns, 3. On the other hand, in any of the large operations, such as amputation of the thigh, 6 deaths only are noted out of the many thousands of cases dealt with. Although a certain amount of fallacy, due to the larger number of trivial cases, may affect these statistics, yet such facts as these not only point to shock as being a more important factor in death during anæsthesia than the anæsthetic itself, but also to the diminution of shock by other anæsthetics in the same way as by alcohol. But it may be said that shock will not explain the occurrence of death during the administration of the anæsthetic, when the operation has not yet been commenced, and the number of these is large, no less than 40 being mentioned in the report. Yet this objection, apparently well founded, is fallacious, because shock or neuroparalysis may arise from emotion or from interference with respiration as well as from operation or accident. In order to understand the causes of death during anæsthesia it will be advisable to consider shortly the modes of death in general.

MODES OF DEATH.

The heart, lungs, and brain have been termed by Bichat the tripod of life, but, as Huxley has very truly observed, the essentials are the heart and lungs. The cerebro-spinal nervous centres are only essential in so far as they maintain the respiratory movements and thus enable the lungs to aerate the blood. The two supports of life thus are the heart and lungs, and death may begin by failure of either. Death beginning at the lungs is usually termed asphyxia, and death beginningat the heart is called shock or syncope.

SYMPTOMS OF DEATH BEGINNING AT THE LUNGS (ASPHYXIA).

The course of death beginning at the lungs is well seen in puppies or kittens drowned in shallow water or suffocated by occlusion of the air passages in other ways. The supply of air to the lungs being cut off the blood gradually becomes more and more venous. The venous blood acts first as a stimulant and then as a paralysant to all the nerve centres, the respiratory, the vaso-motor, the cardio-inhibitory, and the cardio-accelerating. In consequence of this the respiratory efforts are first increased, then the accessory muscles of respiration are called into play, and finally convulsions of the whole body set in. As the nerve centres become paralysed all movements cease, the animal becomes motionless and to all appearance dead; but if the heart be examined it will be found to be still beating. The blood, however, becomes more and more venous. The venous blood acts as a poison to the heart so that its pulsations become gradually slower and feebler, and cease altogether about five minutes after the stoppage of respiration. In this case both heart and lungs are healthy, and if artificial respiration be begun before the heart is too thoroughly poisoned by the venous blood to render its recovery impossible, the blood will be aerated, the heart will continue to beat, the other organs of the body will regain their vitality, and the animal will recover health.

SYMPTOMS OF DEATH BEGINNING AT THE HEART.

When the heart suddenly ceases to beat the circulation is still maintained for about a minute by the elastic pressure of the aorta and arteries. After this time the blood stagnates, and, becoming venous, acts as an irritant to the nerve centres. The effect of this varies according to the condition of these centres. If they are healthy and not already dulled by narcosis through drugs or imperfectly aerated blood previously circulating in them, gasping respiration, with possibly convulsions, may occur, just as in death from the lungs; but if the heart be examined it will be found to be no longer beating. If the nerve centres be dull the respiration will simply stop shortly after the heart, and artificial respiration will not have the same power of resuscitation that it has in death from the lungs.

MECHANISM OF THE HEART.

In order to understand why the heart should suddenly stand still we must consider the mechanism by which pulsations are maintained. It is now generally acknowledged that the muscular fibres both of the heart and bloodvessels have the power of contracting rhythmically independently of nerves; but their contractions are coördinated by nervous arrangements which are partly contained in the heart and vessels themselves, and partly in the central nervous system, and more especially the medulla oblongata. These mechanisms[3] are so complicated that it is impossible, on account of want of space, to discuss them here in detail. Speaking very generally, however, we note that in the heart itself there is one mechanism which causes it to beat more quickly and to contract more strongly, or even to stand still completely in systole. Another mechanism has the opposite action, and causes the heart to beat more slowly, to contract less strongly, to dilate more completely, and even to stand still in complete diastole. Usually these mechanisms act alternately, so that each systole is followed by a diastole and *vice versâ*. It would appear, however, that this arrangement may be disturbed, so that they act together, and then the heart is like the wheel of a steam-engine at the dead point, when no amount of force will make it move. Usually the stimulating mechanism in the heart itself is more powerful than the inhibitory, and irritation of the heart, either mechanical or electrical, will cause it to contract; but during every cardiac cycle there is a time—the "refractory" period of Marey—when irritation of the heart instead of causing contraction, tends to prevent it and prolong the diastole. This refractory period is usually short, but Kronecker and Schmey have found that irritation of a certain point in the septum ventriculorum appears to disturb the coördination of the contracting and dilating mechanisms permanently, so that the heart stands still and cannot be induced to contract by stimulation. Both of these mechanisms are connected with the brain, in which there are inhibitory and stimulating centres, the inhibitory sending impulses to the heart chiefly through the vagus, and the stimulating chiefly through the sympathetic. In the brain, however, the relative strength of the two centres is the reverse of that in the heart, the inhibitory being the stronger of the two, so that cerebral irritation tends to make itself evident by slower pulsation of the heart or stoppage in diastole. The arteries likewise have in themselves a contracting and dilating mechanism, but these also are under the control of the central nervous system.

MECHANISM OF RESPIRATION.

It should not be forgotten that a similar mechanism for respiration exists in the medulla oblongata, consisting of expiratory and inspiratory centres which act alternately under ordinary circumstances, but which may be altered in their relations to one another by poisons or injury, so that respiration ceases entirely.

STIMULATION OF CARDIAC AND RESPIRATORY MECHANISMS.

All the mechanisms in the heart, vessels, and nerve centres, may be first stimulated and then paralysed by venous blood or reflexly by sensory irritations. But the result of stimulation will differ according to (*a*) the strength of the stimulus and (*b*) the condition of each centre. The effects of a strong and weak stimulus are different. Thus a moderate mechanical irritant such as the stroke of a switch acts as a powerful stimulant while a severe blow from a heavy club acts as a paralysant. The inhalation of the dilute ammonical vapour from smelling salts is a powerful stimulant but sudden inhalation of strong ammonia will cause choking and might cause death by neuroparalysis.

[3] The word mechanism has been purposely chosen on account of its indefiniteness as it allows us to include under it various arrangements of muscle, nerve endings, nerve fibres, and nerve cells, without attempting to assign to each the part which it plays in the function performed by the whole.

Digitized by Google

Just as the effects of stimuli on a nerve centre in a certain condition differ according to the strength of the stimulus so the effects resulting from the same stimulus may be of an opposite nature, according as one set of mechanisms or another preponderates.

MODIFICATION BY ANÆSTHETICS OF THE EFFECTS OF STIMULATION.

These mechanisms are not all affected with the same rapidity by anæsthetics, although they are all rendered inactive if the anæsthetics are pushed sufficiently far. Thus it happens that a different result may occur from a sensory stimulus during partial anæsthesia from what occurs either when no anæsthetic has been given or during complete anæsthesia. Thus a powerful irritation of a sensory nerve when no anæsthetic has been given stimulates reflexly both the vagus and vaso-motor centres. The heart is thus slowed, but the fall of blood pressure which this would produce is counteracted, or more than counteracted, by the simultaneous contraction of the arterioles due to stimulation of the vaso-motor centre. The blood pressure may thus remain constant, or even rise instead of falling. When anæsthesia is complete, sensory stimulation has no effect on either centre, and consequently produces no change in the blood pressure. But during imperfect anæsthesia by chloroform Bowditch and Minot have found that the vaso-motor is sooner rendered inactive than the vagus centre, so that a sensory stimulus will tend to stop the heart without contracting the vessels, and will thus lead to a great fall of blood pressure. This unequal failure of nervous mechanisms during anæsthesia they regard, and probably rightly, as one great source of danger when operations are performed in a state of imperfect instead of in complete anæsthesia.

DEATH BEGINNING AT THE BRAIN.[4]

Although death really begins either at the lungs or heart, yet the brain affects both, and we may thus have death from the brain occurring in three ways—(1) through the lungs (coma), with the symptoms of asphyxia; (2) through the heart and vessels (syncope or shock); and (3) through lungs and heart simultaneously (neuroparalysis or shock). When heart and respiration are both affected, they may not be so in the same degree, and thus we may have different varieties of shock, such as the extreme depression, with more or less mental clearness, which occurs after some severe injuries, and the sudden extinction of all the vital processes which occurs after others.

1. Death beginning at the brain is generally a form of death from asphyxia, even when the cerebral injury is sudden or violent, as from a bullet wound. The course of events is nearly the same as that already described under death beginning at the lungs.[5] Death is rapid, if the injury be very severe—e.g., a bullet wound in the brain or a very severe blow on the head; convulsions may occur just as they do in drowning or suffocation. But if the death is slower, as in cases of ordinary apoplexy or of coma from disease or drugs, the gradual accumulation of carbonic acid in the blood acts like an anæsthetic, the cerebral motor centres become paralysed before the respiratory centres cease to act, and thus convulsions do not occur. This is also the case when the motor nerves are paralysed by poisons such as curare, so that the respiratory muscles can no longer obey the stimuli sent to them from the nerve centres. In such cases the timely use of artificial respiration may have most satisfactory results. In poisoning by curare I have by long continued artificial respiration restored an animal to health after it had been apparently dead for four hours, and Schiff has had similar results in animals where respiration had been arrested by slight lesions of the medulla oblongata.

2. The symptoms of the second form have been described under death beginning from the heart.

3. In the third class of cases not only respiration and circulation, but all the functions of the nervous system fail together, the breathing stops, the pulse stops, and the person dies instantaneously and quite quietly without convulsions. This form of death occurs "*far more frequently* than is generally supposed" in cases of hanging, throttling, and strangling.[6] It was certainly new to me to learn, as I did when reading up this subject in one of the best text-books in existence,[7] that nearly one-half of those who die from falling into water are *not drowned*, but are killed by shock, or neuroparalysis, as Casper terms it. A number of the people who died during the destruction of Pompeii died from suffocation, as is evident from the convulsions apparent in the contorted forms which the casts of their bodies present. Some, however, died from shock, and their bodies have remained flaccid and limp.

POST-MORTEM APPEARANCES.

In death by asphyxia, whether it has begun at the brain or lungs, the lungs are found congested; the right side of the heart, pulmonary artery, and great veins are distended with dark fluid blood, and the left side of the heart is empty or nearly so. Capillary ecchymoses occur in the lungs, and there is marked injection of the larynx and trachea. The usual idea that in suffocation the face is bluish-red and swollen, with protruding eyes, is incorrect. Most frequently the countenance after *every kind* of suffocation, and not only where death has occurred from neuroparalysis, differs in no respect from what is observed after other kinds of death.[8] To recapitulate shortly, the appearances observed after death from *asphyxia* are on a large scale precisely the same as those which are seen on a small scale whenever any vessel is obstructed—e.g., by a ligature while the circulation is going on—viz., accumulation of blood on the proximal and diminution of blood on the distal side of the obstruction. In asphyxia the stoppage of the circulation occurs in the minute vessels of the lungs themselves. The right side of the heart and all the vessels connected with it are gorged with blood, while the left side and arteries are empty.

Death from *neuroparalysis* or *shock* "leaves no trace discoverable by the anatomist's knife."[9] The appearances are of a "perfectly negative character," and "not one single organ in the whole body displays any unusual alteration."[10] The lungs are not hyperæmic, and the right side of the heart is not engorged, but both sides are either empty or contain only a small quantity of blood.

What has now been said may possibly enable the readers of THE LANCET report of clinical cases to form their own opinions regarding the mode of death in such cases as are sufficiently reported to classify them according to their causes, and to decide whether they are due to the anæsthetic or the operation, or both.

(To be continued.)

[4] The word "brain" is here used for the sake of brevity and is intended to cover the whole cerebro-spinal and sympathetic system, as the part played by each division of the nervous system cannot be discussed here.

AN INQUIRY INTO THE RELATIVE ADVANTAGES OF VAGINAL HYSTERECTOMY AND THE SUPRA-VAGINAL AMPUTATION OF THE CERVIX IN CANCER OF THE CERVIX UTERI,

BASED ON AN OBSERVATION OF FORTY-THREE CASES TREATED BY ONE OR THE OTHER OF THESE TWO OPERATIONS.

BY ARTHUR H. N. LEWERS, M.D. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL, ETC.

NEARLY two years and a half ago I read a paper before the Royal Medical and Chirurgical Society, in which I recorded my results in nineteen cases of the supra-vaginal amputation of the cervix for cancer of the cervix. Since then I have performed this operation in seven additional cases, making a total of twenty-six operations of this kind. I have also up to the present time (June 3rd, 1895) performed vaginal hysterectomy for cancer of the uterus in twenty-three cases. Six of these were cases of primary cancer of the body of the uterus, and they formed the subject of the paper which I read before the Obstetrical Society of London in December last.[1] In the remaining seventeen cases vaginal hysterectomy was performed for cancer of the cervix. These two series of cases afford material for an inquiry as to the relative advantages of the two operations—the supra-vaginal

TABLE I.—*Twenty-six Cases of Supra-vaginal Amputation of the Cervix for Cancer without a Death.*

No.	Date of operation.	Age.	Complete or incomplete.	Stage of disease.	Recurrence.
1	July 27th, 1885	29	Complete	Moderately advanced	Remained well for six months; then recurrence in pelvis.
2	Aug. 6th, 1885	43	Incomplete	Considerably advanced	—
3	Feb. 12th, 1886	41	Complete	Early	Quite well Jan. 24th, 1888; not seen or heard of since.
4	July 20th, 1886	33	Complete	Considerably advanced (deep conical ulcer)	Remained well and free from recurrence nearly twelve months; then recurrence in pelvis at some distance from the stump.
5	Jan. 7th, 1887	39	Incomplete	Moderately advanced	—
6	March 17th, 1887	42	Complete	Early	Still remains well (May, 1895), more than eight years since the operation. Patient sent to me by Dr. Dundas Grant. Specimen has been shown at the Obstetrical Society and at the Royal Medical and Chirurgical Society.
7	April 5th, 1887	51	Complete	Moderately advanced	Well for six months, then recurrence in stump.
8	Sept. 15th, 1887	52	Complete	Moderately advanced	Remained well nine months, then recurrence in stump.
9	Dec. 6th, 1887	65	Complete	A large, soft, brittle growth protruding through os uteri, and attached a little way up cervical canal, bleeding readily when touched	Remained well more than two years; recurrence took place about six months later.
10	Jan. 16th, 1888	39	Complete; was four months pregnant on admission; abortion induced; supra-vaginal amputation done eighteen days later	Large "cauliflower" growth, chiefly affecting posterior lip	Came up to the hospital soon after the operation; not examined on that occasion; was not seen afterwards. I heard she died in a fainting fit some months later.
11	April 17th, 1888	39	Apparently complete; a previous operation had been done before by another practitioner	Apparently early	Recurrence took place in about six months.
12	May 31st, 1888	42	Complete	Moderately advanced; soft "cauliflower" growth over area, size of half-a-crown, on posterior lip of cervix	Still remains quite well (May, 1895), seven years since the operation. Patient sent to me by Mr. Cursham Corner. Specimen has been shown at the Obstetrical Society and also at the Royal Medical and Chirurgical Society.
13	Sept. 22nd, 1888	32	Apparently complete; the operation was done nine weeks after a confinement at term; symptoms had been present during pregnancy	Considerably advanced; large mushroom-shaped growth, chiefly involving anterior lip	Recurrence in stump in three months.
14	March 28th, 1889	37	Complete	Advanced	Well three months after operation; not seen since.
15	May 2nd, 1889	31	Complete	Moderately advanced; soft growth chiefly affecting posterior lip	Not seen since she left the hospital.
16	August 26th, 1889	40	Complete; was three months pregnant at time of operation; miscarried two days after it; Douglas's pouch slightly opened; cervix cut off with the cautery	Moderately large "cauliflower," chiefly affecting posterior lip	Still remains quite well (May, 1895), more than five years since the operation. She has attended regularly at the London Hospital about once a month since the operation. Specimen has been shown at the Obstetrical Society and at the Royal Medical and Chirurgical Society.
17	Feb. 18th, 1890	53	Complete	Moderately advanced "cauliflower" growth, size of half a walnut, springing from right side of cervix just within os uteri	Still remains well, more than five years since operation. She was sent to me by Dr. Godson. I last saw her on June 1st, 1895. Specimen has been shown at the Royal Medical and Chirurgical Society.
18	May 7th, 1891	38	Complete	Moderately advanced; anterior vaginal wall slightly infiltrated; naked eye appearance that of cancerous growth; microscopically only a glandular structure seen	Was well for more than a year; then symptoms of recurrence, and the last time I saw her there was a large, evidently malignant, ulcer at the top of the vagina. It is interesting to observe that the microscopical characters of the growth in this case were not such as to make it clear that the case was one of cancer. The recurrence, however, placed the nature of the case beyond doubt.
19	Feb. 18th, 1892	—	Incomplete	Advanced	—
20	Jan. 29th, 1893	37	Complete	"Cauliflower"; moderately advanced	Still remains well (June, 1895), more than two years since the operation. Patient sent to me by Mr. Garry Simpson of Acton.
21	Feb. 8th, 1893	60	Complete	Am doubtful as to malignancy, though clinically the symptoms and signs were suggestive of cancer	No sign of recurrence.
22	March 22nd, 1893	47	Complete	Moderately advanced	Still remains well (June, 1895), more than two years since operation. This patient was sent to me by Dr. Godson.
23	Jan. 18th, 1894	32	Complete	Large conical ulcer	Still remained well (May, 1895) when I examined her at the London Hospital.
24	Feb. 6th, 1894	—	Complete	Am doubtful as to malignancy, though clinical appearances suggestive of cancer	—

TABLE I.—*Twenty-six cases of Supra-vaginal Amputation of the Cervix for Cancer without a Death*—(continued).

No.	Date of operation.	Age.	Complete or incomplete.	Stage of disease.	Recurrence.
25	Feb. 20th, 1894	—	Incomplete; the uterus was much enlarged, apparently by fibroids; when the cervix was cut off at level of internal os it was evident that there was some malignant growth above the line of section. The patient refused to have the remainder of the uterus removed by a combined operation; the body of the uterus was too large to have removed per vaginam.	Moderately advanced	—
26	Jan. 10th, 1895	46	Complete	Conical ulcer	Remains well at present. The patient was sent to me by Mr. Vernon of Poplar.

TABLE II.—*Twenty-three cases of Vaginal Hysterectomy for Cancer, with three Deaths.*

No.	Date of operation.	Place.	Part affected.	Complete or incomplete.	Immediate result.	Subsequent history.
1	March 1st, 1886	London Hospital	Primary cancer of the body	Complete	Recovered	Well for nearly a year, then recurrence.†
2	—	London Hospital	Cancer of cervix	Complete	Died.*	—
3	Nov. 7th, 1889	London Hospital	Primary cancer of the body	Complete	Recovered	Known to be well Oct., 1893, about four years after the operation; not seen since. For full record see THE LANCET.‡
4	Oct. 23rd, 1890	London Hospital	Cancer of cervix	Complete	Recovered	Still remains well (May, 1895), four years and a half since the operation; I see her regularly at the London Hospital.
5	March 17th, 1892	London Hospital	Primary cancer of body	Complete	Recovered	Remained well for more than two years and a half; early this year (1895), and before it was three complete years since the operation, she came to the hospital with undoubted recurrence.
6	June 16th, 1892	Private (with Mr. Russell of Forest-gate)	Cancer of cervix	Complete	Recovered	Remained well more than two years after the operation; recurrence, however, took place early in the third year—i.e., about August, 1894.
7	Feb. 1st, 1893	Private (with Mr. Stott of Highgate)	Primary cancer of body	Complete	Recovered	Remains well (May, 1895).
8	June 8th, 1893	London Hospital	Primary cancer of body	Complete	Recovered	Remained well (May, 1895) when she came up to the London Hospital and I examined her. Patient sent to me by Mr. Best of Dover.
9	July 20th, 1893	London Hospital	Cancer of cervix; large "cauliflower"-like growth of posterior lip	Complete	Recovered	Remained well for a little more than a year, then recurrence.
10	Aug. 4th, 1893	London Hospital	Cancer of cervix; large "cauliflower" growth of posterior lip	Complete	Recovered	Recurrence took place in less than a year, and the patient died on Feb. 23rd, 1895.
11	Aug. 21st, 1893	London Hospital	Primary cancer of body	Complete	Recovered	Quite well Oct. 11th, 1894; not seen or heard of since.
12	Aug. 28th, 1893	London Hospital	Cancer of cervix	Incomplete; the perimetric tissue evidently partly involved	Recovered	Sent to me by Dr. W. Duncan when Middlesex Hospital was closed.
13	Feb. 1st, 1894	Private	Cancer of cervix	Complete	Died	—
14	Feb. 22nd, 1894	London Hospital	Cancer of cervix; large "cauliflower"	Apparently complete	Recovered	Recurrence took place in August, 1894.
15	Feb. 27th, 1894	Private (with Mr. Howse and Dr. Williams of Barking)	Cancer of cervix; "mushroom"-shaped growth	Complete	Recovered	Remains well at present (May, 1895).
16	Aug. 13th, 1894	Private	Cancer of cervix; large "cauliflower" with a nodule in left broad ligament	Seemed complete	Recovered	Symptoms of recurrence within a few weeks of patient's return home.
17	Aug. 16th, 1894	London Hospital	Cancer of cervix	Incomplete	Recovered	—
18	Aug. 30th, 1894	London Hospital	Cancer of cervix; large "cauliflower"	Complete	Died	—
19	Oct. 18th, 1894	London Hospital	Cancer of cervix; ulcerative type	Complete	Recovered	Well at present (May, 1895). Sent to me by Mr. Howse of Barking.
20	Dec. 6th, 1894	London Hospital	Cancer of cervix	Incomplete	Recovered	—
21	Feb. 14th, 1895	London Hospital	Cancer of cervix	Complete	Recovered	Well at present (May, 1895). Sent to me by Mr. Cory of Bournemouth.
22	April 25th, 1895	London Hospital	Cancer of cervix; large "cauliflower"	Doubtful	Recovered	—
23	June 1st, 1895	Private (at Fitzroy House). Sent to me by Mr. Garry Simpson of Acton	Cancer of cervix; growth entirely in canal. Body of uterus greatly distended, containing about half a pint of fœtid pus	Complete	Recovered	—

* Died on the second day with gradual heart failure and œdema of lungs; no local complication.

amputation of the cervix on the one hand and vaginal hysterectomy on the other—in cases of cancer of the cervix. If I were only able to bring forward a series of cases of one of these operations, it might appear as if I were, to some extent at least, prejudiced in favour of the operation performed in the series I was bringing forward. As, however, I bring forward a series of each of these operations, I think I may fairly claim that I approach an inquiry into their relative merits without any bias. As is well known, there has been a considerable difference of opinion as to which operation should be the recognised routine treatment for cases that are not too far advanced for operation. There is undoubtedly at the present time, so far as a mere enumeration of names is concerned, a majority in favour of treating all such cases by total extirpation. If we consider what are the chief points for comparison in operations for cancer of the cervix we find the principal ones to be three: (1) the mortality of the operation; (2) the amount of mutilation involved; and (3) the length of time for which the patients operated on remain free from recurrence.

1. *Mortality.*—In bringing forward data on this point it seems to be the fairest way to mention *all* the cases in which a radical operation has been performed for cancer of the uterus. My total number of radical operations for cancer of the uterus has been 49, with 3 deaths, a mortality of 6·1 per cent.; 23 were vaginal hysterectomies, and of these 3 died; and 26 were supra-vaginal amputations of the cervix, and all these recovered. Of the 3 deaths among the cases of vaginal hysterectomy the first was from shock, the patient dying on the second day with gradual heart failure and œdema of the lungs; there was fatty degeneration of the heart. There was no local complication such as hæmorrhage or peritonitis. It appeared that she was unable to stand the shock of so severe an operation. The second death was from hæmorrhage. In this case there had been a deep laceration of the cervix quite up to the vaginal reflection on the left side and there was a firm cicatricial band running outwards from the laceration. This prevented the uterus being properly drawn down, and when the cervix was being freed in the neighbourhood of the laceration a large vessel, probably the uterine artery itself, retracted at once out of reach, and though it was ultimately secured a fatal quantity of blood had been lost. I consider the lesson of this case to be that either the supra-vaginal amputation of the cervix or vaginal hysterectomy is either absolutely contra-indicated, or becomes, at all events, an extremely hazardous operation if for any reason whatsoever the uterus cannot be fairly drawn down to the outlet of the vulva. This may happen on account of old perimetritic adhesions, or, as in this case, in consequence of cicatricial bands in the neighbourhood of a deep laceration, and equally so if there is extension of the disease beyond the limits of the uterus into the broad ligaments or utero-sacral ligaments. In all such cases, if the uterus is tethered so that it cannot be brought down fairly into reach, either operation becomes on this account alone extremely dangerous. The third death was from peritonitis, due, I feel satisfied, to an infection of the peritoneum by the breaking down of plastic adhesions in the neighbourhood of the wound when the pressure forceps were being removed. Up to and including this case I was in the habit of removing the pressure forceps at the end of forty-eight hours, by which time there is no risk of hæmorrhage. Since this case I have left them on, and also left the gauze plug undisturbed till the fourth day, by which time the adhesions shutting off the peritoneum must be considerably stronger than on the second day. As my list of 49 cases includes all the cases in which I have performed either vaginal hysterectomy or the supra-vaginal amputation of the cervix for cancer, it includes my early cases as well as those operated on quite recently; and, although I regard a mortality of 6·1 per cent. as satisfactory, and, indeed, encouraging, I think I may fairly expect that, profiting by the experience already gained, the mortality in a future series may be even less. My own feeling certainly is that, although vaginal hysterectomy for cancer is not a very dangerous operation, it is still distinctly more dangerous than the supra-vaginal amputation of the cervix. It is scarcely necessary, however, to mention that there are others who consider the supra-vaginal amputation as dangerous or even more dangerous than vaginal hysterectomy. I do myself consider that the supra-vaginal amputation, properly performed, is as difficult as vaginal hysterectomy; and, as regards the latter operation for cancer of the cervix, that, generally speaking, the only difficult part about it consists in the preliminary liberation of the cervix.

2. *Mutilation.*—As regards the amount of mutilation incidental to the two operations, obviously vaginal hysterectomy involves much more mutilation than the high amputation of the cervix, and still more so if the uterine appendages are removed at the same time, as is the practice of some operators. After the supra-vaginal amputation of the cervix the rest of the uterus generally remains freely movable, and, if the menopause has not occurred, menstruation may continue normally, and even pregnancy may occur, though I have not met with an instance of this among my own cases. The whole organism of the woman is not profoundly altered as it must be when the entire uterus is removed. After the supra-vaginal amputation the floor of the pelvis remains nearly in the same condition as before, while after vaginal hysterectomy it is necessarily much altered. Adhesions necessarily form to close the wound through which the uterus has been removed. Coils of intestine or portions of omentum may adhere to the scar, and may subsequently become a source of discomfort or of actual danger to the patient. On vaginal examination a condition of more or less fixity of the tissues at the top of the vagina is often felt after vaginal hysterectomy. Shock varies largely in proportion to mutilation; the more mutilation the more shock. After the high amputation I have not met with any degree of shock worth mentioning. It is quite true that in cases of vaginal hysterectomy also there is generally no shock. At the same time it appears to me that the latter operation is a more searching test of the resisting powers of the patient; if these are all that can be desired there will be no shock, but if they are seriously impaired there may be a severe or even fatal degree of shock. I have already mentioned a case (No. 2, Table II.) in which there was fatty degeneration of the heart, and in which the patient's death seemed solely attributable to the fact that her vitality was unequal to the strain of so severe an operation. In other words, patients can stand the supra-vaginal amputation of the cervix who would succumb if submitted to vaginal hysterectomy.

3. *Length of time patients remain free from recurrence.*—The next point—and it is an extremely important one—concerns the remote result in each series of cases. Are patients with cancer of the cervix ever cured by either supra-vaginal amputation of the cervix or vaginal hysterectomy? In order to find a satisfactory answer to this question there are at least two essential points. 1. In any case operated on for cancer where no recurrence has taken place after some years, and where, therefore, it is claimed that the patient has been cured by the operation, it is essential to have indisputable evidence that the growth removed was really malignant. The best way of doing so is for the specimen to be exhibited to the observation of independent experts, as may be done by showing the specimen before one of the medical societies. This has been done in all my cases of supra-vaginal amputation in which the disease has not recurred. 2. The second point—and it is one which involves the coöperation of the patient or her medical attendant or of both—is that it should be possible to keep the patients who have been operated on under observation. Only those who have tried it are aware of the difficulty of doing this, more especially among patients of the hospital class who are so constantly changing from one place to another, often leaving no address by which to trace them. I have tabulated in chronological order the 26 cases in which I have performed the supra-vaginal amputation of the cervix. An analysis of it brings out the following conclusions. Taking account only of those cases in which a period of two or more years has elapsed since the operation it will be seen that there are 22 cases in this category. Of these 22 cases three (Nos. 2, 5, and 19) were incomplete; one case (No. 21) was of doubtful malignancy. Subtracting these, it will be found as regards the remaining eighteen cases that eight (Nos. 1, 4, 7, 8, 9, 11, 13, and 18) were known to have had recurrence. In six of these (Nos. 1, 4, 7, 8, 11, and 13) recurrence took place within *one* year of the operation; in one case (No. 18) within *two* years of operation; and in one case (No. 9) within *three* years of operation. In the large majority of cases, then, recurrence, if it was going to take place, occurred within one year of the operation. In four of the eighteen cases the patients were lost sight of; these were Nos. 3, 10, 14, and 15, and were all hospital cases. They, of course, may or may not have had recurrence. In the remaining six cases, out of the 18 (Nos. 6, 12, 16, 17, 20, and 22) the patients are still quite well at intervals of 8, 7, 5, 5 2, and 2 years respectively—that is, 33 per cent. remain well. Of the cases 23 to 26, one (No. 25) was incomplete; one (No. 24) was of doubtful malignancy; and two

Digitized by Google

(Nos. 23 and 26) are still quite well, but it is less than two years since the operation. I have also tabulated in chronological order the 23 cases in which I have performed vaginal hysterectomy for cancer of the uterus. Of these 23 cases 6 were cases of primary cancer of the body of the uterus, and do not concern this part of the question, though it seems right to include them when estimating the mortality. Subtracting these and the three fatal cases, there remain fourteen vaginal hysterectomies for cancer of the cervix. Four of these (Nos. 12, 17, 20, and 22) were incomplete; that is, although the whole uterus was removed I had reason to think that infiltrated tissue outside the uterus had been left. Of the remaining ten cases, five (Nos. 6, 9, 10, 14, and 16) were known to have had recurrence—in No. 6 within three years of operation; in No. 9 within two years; and in Nos. 10, 14, and 16 within one year. Of the remaining 5 cases, No. 4 remains well four years and a half since operation; No. 15 remains well one year and three months since operation; and Nos. 19, 21, and 23 remain well, but it is less than a year since operation. So that, although 5 out of 17 operated on by vaginal hysterectomy remain well, or 29·4 per cent., in only 1 case of those 5 has a period of two years or more elapsed since the operation. Only 5·8 per cent. of the cases then are in the class of two years' standing and upwards since the operation. In the series of cases of supra-vaginal amputation of the same standing 33 per cent. remain well.

The only conceivable explanation, as it seems to me, of the above figures, which show such favourable results for the supra-vaginal amputation and such unfavourable results as regards recurrence for vaginal hysterectomy, is that in the cases operated on by the supra-vaginal amputation the disease was in an earlier stage than in the cases treated by vaginal hysterectomy. The ultimate conclusions which a consideration of these two series of cases seems to warrant are: (1) that, when the disease is in a stage in which a cure by operation may be hoped for, the supra-vaginal amputation performed according to the method I adopt (which is fully described in my paper published in the Transactions of the Royal Medical and Chirurgical Society[2]) gives the patient as good a chance of cure as vaginal hysterectomy, and with somewhat less risk; and (2) that when the disease has become too far advanced for complete removal by the supra-vaginal amputation of the cervix it has also—at least, in the large majority of cases—passed beyond the reach of cure by vaginal hysterectomy. In the uteri I have removed for cancer of the cervix I have never met with an isolated simultaneous malignant deposit in the body of the uterus. In one case (No. 19) where there was a white nodule the size of a pea in the wall of the body of the uterus it proved on examination with the microscope to be only a small fibroid. This is an important point, because if it were the fact that isolated malignant growths occur at all commonly in the body of the uterus in cases of cancer of the cervix it would be a conclusive argument in favour of always performing vaginal hysterectomy. Such an association, however, if it really ever occurs, appears to be so rare that it may be neglected for practical purposes. It may be objected that my comparison of vaginal hysterectomy with the supra-vaginal amputation is unfair, because hysterectomy was generally adopted in cases rather more advanced than those in which the supra-vaginal amputation was performed. But I think the comparison is a proper one, more especially on this very ground, since the point for consideration is whether vaginal hysterectomy is *superior* to the supra-vaginal amputation, not whether it is as good as the supra-vaginal amputation. Obviously, among my six cases of supra-vaginal amputation, in which from two to eight years have elapsed without recurrence, the same result would have followed if vaginal hysterectomy had been performed instead. But there would clearly have been a fallacy in considering such a result as an argument in support of the superiority of vaginal hysterectomy. Vaginal hysterectomy must always be at least equal to the supra-vaginal amputation from the point of view of recurrence. The point to be decided is whether it is superior to the supra-vaginal amputation. One way in which this superiority might be proved would be that vaginal hysterectomy should be effectual as a means of cure in cases more advanced than those in which the supra-vaginal amputation has been shown to be efficacious. My own series of cases tells the other way, and goes to show that when the disease is too far advanced to be cured by the supra-vaginal amputation it has passed beyond the reach of cure by any operation whatever.

Wimpole-street, W.

[2] Vol. lxxvi., p. 101.

A CASE OF CHRONIC DYSENTERY OF MORE THAN FOUR YEARS' STANDING CURED BY REST IN BED AND A MILK DIET.

BY W. HALE WHITE, M.D.,
PHYSICIAN TO GUY'S HOSPITAL.

ALMOST the only form of dysentery we see in England is that which has become chronic. Often the sea voyage and the change of climate suffice to cure it, but when this is not so the treatment becomes a matter of great interest to us here. The chronic form is so different in its symptoms from the acute variety that we ought probably to regard it more as a chronic colitis left by the previous acute attack than as a specific disease, just as those patients whom we see in this country with anæmia subsequent to tropical malaria are, when examined in England, to be considered as suffering rather from the anæmia left as a result of the invasion of the blood by the plasmodium malariæ than from the actual presence of the parasite. Even if the amœba of dysentery be found in the stools passed in England it does not follow that this view is wrong, for the creature may be powerless for harm here, and further we know that long after an attack of diphtheria, diphtheritic bacilli may be met with in the mouth, and the bacilli of enterica may be found in the pus of an abscess which forms in a patient who has suffered from this disease months before. It has often seemed to me that the treatment of intestinal affections is frequently too active, and that the great principle of giving an inflamed part rest is neglected; all sorts of drugs, many of which may cause enteritis, are given, and it is forgotten that lying in bed is one of the best ways of keeping the bowels quiet. The simplest way to give the surface of the colon freedom from irritation is to feed the patient on small quantities of milk at frequent intervals, say every two hours, a total of two pints a day for an adult being quite enough. If undigested curds are passed in the motions it may be peptonised; if the monotony of the taste is disagreeable it may be flavoured with a very little coffee. Should this diet lead to much constipation from four to eight ounces of olive oil thrown up the rectum every third day will give relief. Complete rest in bed is essential. I have seen this treatment cure long-standing cases of simple colitis without the administration of any drugs. In a very bad case of membranous colitis which had lasted ten years I have recently carried out the principle of giving rest so far as to have a right colotomy done, all the fæces for six weeks being allowed to pass through the artificial anus, thereby giving the colon absolute rest. When I suggested this in THE LANCET[1] Mr. Skene Keith wrote to say that he had adopted the same procedure. The principle of giving the colon rest was acted upon in the case described below. It will be observed that the patient had been in England, suffering from chronic dysentery four years and a quarter, that he had been going to many medical men who had given him all sorts of drugs, but that he had never been kept in bed for months on a milk diet. Nevertheless, this simple plan succeeded so well with him that although it is ten months since he was allowed to get up he has had no sign of a relapse and is now in robust health. That this is the correct treatment for chronic dysentery is borne out by such great authorities on the subject as Dr. Ward,[2] who says that most of the vaunted remedies are useless, but rest in bed and milk are essential for success; and Mr. Harry Leach,[3] who says the same, and adds that success with drugs is the exception, and that those cases do best which are least drugged. My reasons for publishing my case are to redirect attention to the papers of Dr. Ward and Mr. Harry Leach—and this is the more important as the subject of the treatment of chronic dysentery is almost ignored in many books which

deal specially with dysentery—and to show that when the disease has lasted many years the patient may be restored to complete health. The milk diet should be continued until the pain, diarrhœa, and passage of blood or mucus have all ceased and formed motions have been passed for some time; the patient should not get up till at least a fortnight or three weeks after he has passed from milk to farinaceous diet. It will be noticed that the restricted diet was continued although the patient lost weight; provided that he is not allowed to become too weak this is of little importance compared with the advantage gained from rest to the colon.

On March 17th, 1894, Dr. H. J. Dring asked my opinion on the case of a patient aged thirty-three years. He was originally a healthy subject. In 1882 he left England for Minnesota, where life was rough and work hard, but except for a slight attack of malaria he kept well. In 1885 he went to Fiji; he was never well there and had dysentery severely in 1888. As he got no better he was sent to Melbourne and admitted into the hospital, where he was twelve weeks. When he left there he was better, but he relapsed immediately, and gradually getting worse and worse he finally started for England, arriving at Christmas, 1889. From then till 1894 he went to numerous medical men, who gave him drugs, but none of them put him to bed for long together, and although often the dysentery would entirely disappear for a short time it always returned, and he was consequently quite unable to follow any occupation, and had had to resign various posts. When I saw him the bowels were open four or five times a day, the motions contained much mucus and blood, he complained greatly of dull abdominal pain, especially in the left iliac region, his tongue was covered with a thick white fur, he was very anæmic, sallow, and wasted. He weighed 11 st. 2 lb., his height being 6 ft. 1½ in. I gave it as my opinion that the only treatment likely to cure him was complete rest in bed and milk diet for many months, and he consented to undergo it. He was put to bed on March 31st, 1894. On this day the bowels were opened five times, and the stools contained much blood and mucus, with a few small, hard lumps of fæces; there was much pain before the act of defecation. Some observers thought amœbæ could be seen under the microscope in the fæces, but others could not find them. The patient was allowed no food except two pints of milk a day. He was ordered ten grains of ipecacuanha powder thrice a day; and twenty grains of carbonate of bismuth, twelve minims of tincture of opium, twenty grains of compound tragacanth powder, and water to make one ounce thrice a day. The accompanying table shows the frequency with which the

bowels were open. On April 6th the motions contained no mucus, but still a little blood. The pain was better. The mixture was stopped and the ipecacuanha was given in the form of a five-grain pill thrice a day as the patient was very sick. On April 10th, as the pills were passed unchanged, the ipecacuanha was put in cachets, but he continued to be sick, and so the ipecacuanha was in a few days left off. On April 16th there was still some blood and mucus in the motions and some pain in the abdomen. He was put upon a mixture containing ten grains of carbonate of bismuth, ten grains of bicarbonate of sodium, and ten minims of liquor morphiæ hydrochloratis. On April 25th the patient was allowed four oysters a day in addition to his milk. On May 1st he passed a formed motion for the first time. The pain in the side had decreased and the mucus and blood were much less abundant and less frequent than formerly. By May 25th the motions were always formed. Often there was neither blood nor mucus, and when either was present the amount was very slight. The pain had almost disappeared. From this date the progress was uninterrupted. Blood and mucus were only seen in the motions on one or two occasions. By July 3rd he had improved much in all respects. He was allowed some coffee. On July 27th the improvement continued. He was allowed some custard. On Aug. 22nd bread-and-milk made without crust and a little bread-and-butter were added to his diet. On the 27th he got up for a short time, having been in bed continuously for five months. His weight was 9 st. 6 lb. He thought he probably weighed less a month before. On Sept. 8th he was allowed fish; on the 14th he went out for the first time; and on the 21st he took ordinary meat. On Oct. 8th he went away into the country. He was directed to keep warm, to lie about as much as possible, to walk but little, and to avoid rich dishes, indigestible food, fruits, and most vegetables. On Dec. 2nd he wrote from the country saying that he had been "getting on steadily, gaining in strength and weight. I turned the scale at 12 st. 11 lb. yesterday, and can walk a good deal without getting tired." He went on to say that he had been most careful in his diet, and that he had lived chiefly on milk. During the spring of 1895 he was to all intents and purposes quite well, playing golf daily and taking ordinary plain food; and in May he went back to business, just thirteen months after the treatment began. He is still in excellent health. During the time he was under treatment an occasional enema of olive oil was given when it appeared necessary on account of constipation. None of the medicines above mentioned, nor some de-emetised ipecacuanha which was ordered, were continued for long, for it was found that on the whole he did better when he was not taking drugs.

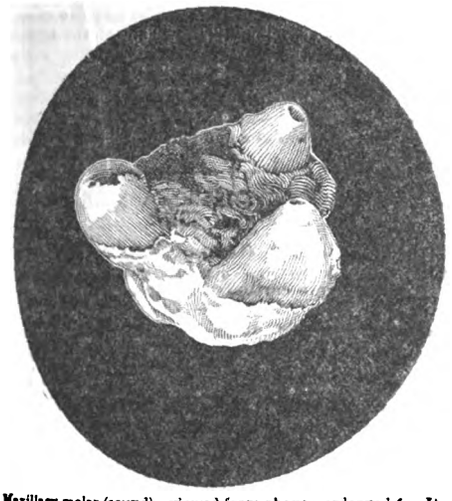
Harley-street, W.

ON MALIGNANT DISEASE OF THE PERIDENTAL MEMBRANE.

BY A. HOPEWELL SMITH, L.R.C.P. LOND., M.R.C.S., L.D.S. ENG.

DURING the course of some recent investigations in the subject of the patho-histology of the peridental membrane I found among my specimens several marked examples of a new growth intimately associated with and springing from the fibrous periosteum of the teeth—a condition which seems to have escaped the attention of the writers of surgical and dental text-books. These periosteal tumours present on examination appearances which warrant more than a passing notice and afford a subject of great interest and importance to general and dental surgeons alike. The cases under consideration are not absolutely unique. For instance, Mr. Oakley Coles, at the annual meeting of the British Dental Association held at Cambridge in 1885, mentioned that he had at a previous meeting of the Odontological Society of Great Britain, exhibited a specimen of round-celled sarcoma attached to a molar tooth, the microscopic examination of which had been made by Dr. Klein. As a result of the study of my morbid anatomy specimens, of which I possess more than half a dozen, I have been induced to place on record my observations on this particular and somewhat rare affection.

To those unfamiliar with the microscopical appearances of the peridental membrane a brief description of its histology is needful for a larger comprehension of the patho-histology of the disease. The alveolo-dental periosteum is a thin layer of connective tissue which surrounds the roots of teeth and occupies a position between them and their osseous sockets. It consists of bundles of large white connective-tissue fibres arranged chiefly in a transverse direction, and is, in fact, "much like any ordinary fibrous membrane,"[1] being freely supplied with bloodvessels and nerves. The cellular elements vary considerably, and include cementoblasts, osteoblasts, osteoclasts, and fibroblasts, together with cells and tissues of



[1] Tomes: Dental Anatomy, p. 93. 1894.

Digitized by Google

an "indifferent" nature.[1] In addition, there are occasionally found cementoclasts, calcospherite spherules, and the so-called "lymphatic spaces" described by Dr. G. V. Black. Of all these the fibrous tissues and fibroblasts predominate.

The chief points of interest in connexion with these peridental tumours are that they are found in connexion with the roots of sound teeth, and that their characteristics are those of round-celled (alveolar) sarcomata.

FIG. 1.

Maxillary molar (sound); viewed from above; enlarged ½. It shows the growth in its early stage, springing from the peridental membrane of the region between the roots.

1. *Seats of occurrence.*—The growth is confined, as its *locus principii*, to the periosteum of the molar teeth, the maxillary being much oftener affected than the mandibular series. It is generally seen to rise from a point situated at the junction of the roots with the body of the tooth (Fig. 1); but it may have its origin from the sides of one or even two roots (Fig. 2). Later, it generally fills up the whole of the inter-radicular region of the tooth (Fig. 3).

2. *Macroscopical appearances.*—The tumours vary in size from that of a split pea to a small nut, and have a smooth,

FIG. 2.

Maxillary molar (sound); side view; enlarged ½. It shows the growth springing from the sides of the two buccal roots. A more advanced stage than Fig. 1. There is a slight deposition of tartar on the distal aspect of the tooth.

convoluted, rarely ragged surface. They are firm to the touch and are of a deep-red colour. The teeth themselves are non-carious and exhibit in their hard parts no traces of disease except slight attrition of their cusps and (in some cases) absorption of the apices of the roots. They are markedly loose, and signs of chronic inflammation of the periosteum, accompanied by an accumulation of tartar, are often noticed.

3. The *etiology* of the disease is obscure; but there seems to be a predisposition on the part of the growths to attack the fibrous membranes of the teeth of females about the period of the menopause. Long-continued and powerful friction, as shown by the wearing down of the cusps, is probably the exciting cause.

FIG. 3.

Portion of right maxilla excised for malignant disease; distal view; enlarged ½. It shows the first maxillary molar *in situ* with its peridental membrane greatly increased in size by the growth, and also the secondary infiltration of the neighbouring parts. The tooth is sound, but loosened to a considerable degree. The sound canine tooth is seen in position at the back of the figure, the roots of the two bicuspids occupying the interspace. From original photographs.

FIG. 4.

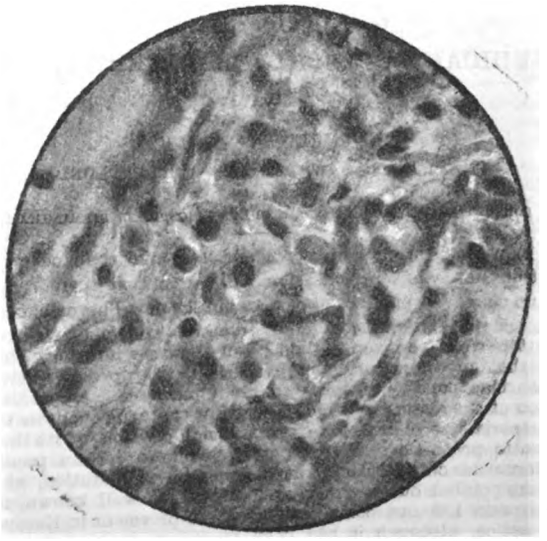


Photo-micrograph of a section (× 500 diam.) of a peridental sarcoma exhibited at a recent meeting of the Odontological Society of Great Britain.

4. The *subjective symptoms* point chiefly to long-continued sharp pain, increased on pressure, the course of the disease lasting sometimes several months. The pain is excruciating at times, and such as to render necessary immediate extraction of the loosened organ.

[1] Black: A Study of the Histology of the Periosteum and Peridental Membrane, p. 72. 1887.

Digitized by Google

5. *Objective symptoms.*—On examining the mouth, at first there is sometimes almost entire absence of swelling or of any usual inflammatory signs, and the tissues are not markedly indurated. There may be slight suppuration. If the disease is not far advanced diagnosis is only complete after removal of the tooth. Later, well-marked symptoms of malignancy appear.

6. *Microscopical appearances.*—The growths consist of masses of cells held together by a fine network of fibrous tissue which is very dense here or very loose there, and is in some places apparently undergoing fibrification or chondrification. In the centre of the growth this network is scanty, but the intercellular tissue is conspicuous outside. Vessels are scanty in the centre and have extremely thin walls; they ramify among the cells. In the outer portion they are larger (but not dilated) and have normal walls. The cells themselves are for the most part rounded in shape and considerably larger than red blood-corpuscles (Fig. 4). They contain one or more nuclei and are devoid of any definite cell wall. Great numbers of spindle cells exist. There is little hæmorrhage into the tissues, probably because of the small size of the growth, and because it has not advanced sufficiently to allow of large hæmorrhages to take place in its substance; but small extravasations of blood corpuscles are noticed here and there. Microscopically the growth is practically indistinguishable from granulation tissue, as has been pointed out by Mr. Knyvett Gordon; considered from a clinical aspect, however, there can be no doubt as to its malignant nature, as Fig. 3 shows. The jaw was excised for malignant disease of the antrum by Mr. W. J. Pilcher of Boston, to whom I am indebted for the specimen. The photograph exhibits the first right maxillary molar *in situ*, with its peridental membrane greatly enlarged by the new growth. Infiltration of the surrounding parts has taken place, the gum, antral mucous membrane, and alveolar process being alike affected, and the latter partially absorbed. There is also absorption of the apical regions of both the labial roots. The patho-histology of this growth is identical with that of the isolated cases already mentioned, and from the evidence at hand it seems to be clear that the latter are only earlier stages of the former.

To sum up, it may be said that sarcomatous disease of the peridental membrane is not rare in its earlier forms, but that it is very seldom met with in an advanced condition; and that removal of the molar tooth fortunately cuts short its career if taken sufficiently early, but if it is allowed to continue it constitutes another starting-place for malignant disease of the maxillæ.

Boston, Lincs.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TINCTURE OF CUSPARIA.

BY SIR JAMES SAWYER, M.D., F.R.C.P. LOND., F.R.S. EDIN.,
CONSULTING PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

FEW drugs are better known and less used than cusparia. I think many of our profession will agree that there should be a spirituous tincture of cusparia in the new Pharmacopœia. In officinal tinctures of mild aromatic and non-astringent bitters we are not too well off; and a watery infusion, which is the only preparation of cusparia in the present British Pharmacopœia, is unwieldy for many purposes. A consideration of the history and constitution of the drug suggests that cusparia has claims to a professional revision of its therapeutic properties. Perhaps it is owing to certain peculiar circumstances of fraudulent commercial substitution, which were pointed out long ago and which are well known, that cusparia has not come into usual employment in European practice, although it has been much vaunted as the chief ingredient in a popular cordial, and although it appears to have found extensive therapeutic consumption in South America and elsewhere. I have been prescribing a tincture of cusparia bark, which I have had made with proof spirit, and of the strength of two and a half ounces of the bark to one pint, and I have directed its preparation in a manner similar to that given in the officinal directions for tincture of cascarilla. Recent researches (1892) of Beckurts and Nehring show that cusparia bark contains, besides a volatile oil and other constituents, four alkaloids—namely, galipine, galipidine, cusparine, and cusparidine—all of which are crystallisable bases. I think it will be found that a proof spirit tincture would better represent the essential constituents of the drug than an aqueous preparation, such as an infusion. The profound and practical Paris, in his classic "Pharmacologia," wrote of cusparia bark: "Its active matter is taken up by cold and hot water, and is not injured by long decoction, but the addition of alcohol precipitates part of the extractive. Alcohol dissolves its bitter and aromatic parts, but proof spirit appears to be its most complete menstruum." I find that a weaker tincture than that which I have indicated—namely, of the strength of one ounce of cusparia to one pint of proof spirit—is given as a non-officinal formula by Beasley.

A CASE OF FORWARD DISLOCATION OF THE SEMI-LUNAR BONE.

BY LEONARD P. GAMGEE, F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM; SURGEON TO THE CHILDREN'S HOSPITAL, BIRMINGHAM.

A MAN aged fifty-two was admitted to the General Hospital, Birmingham, on April 9th, 1895, complaining of a swelling over the front of the left wrist and of inability to flex the joint. He stated that four months previously, while working in a mine, he was standing with his back to the wall, with his left elbow flexed and with the back of his left arm pressing against a beam which projected from the wall. While he was in this position a truck came along and struck his left hand in such a way that his wrist was forcibly hyperextended. He found, immediately after the accident, that he was unable to flex his wrist, and very soon a great deal of swelling appeared all round the joint, both back and front. This general swelling subsided during the next fortnight. At the end of that time the condition was the same as on his admission. When he was admitted the following conditions were present. The power of extension of the left wrist was normal, but the joint could not be flexed beyond the horizontal position. On the front of the carpus in the middle line was a hard and fixed swelling, apparently immediately under the skin. From the size and position of the swelling I diagnosed that it was one of the carpal bones—probably the os magnum—dislocated forwards, and, from the fact that the patient felt numbness and tingling along the palmar surfaces of the first three fingers, that the median nerve was stretched over the surface of the bone. It was quite impossible to reduce the dislocation, and so two days after his admission I made a longitudinal incision over the swelling and found it to be caused by the semilunar bone, which had been dislocated forwards and then displaced downwards over the os magnum, the median nerve being stretched over the front of the bone. The nerve was freed and the bone removed, the wound healing by primary union. I last saw the patient on June 11th and found that the movements of his left wrist-joint were perfect, the left hand being practically as useful as the other. Subluxation backwards of one of the carpal bones, especially of the os magnum, is not very uncommon and is generally caused by forcible flexion of the hand. Forward dislocation of one bone, unless compound, is, on the contrary, extremely rare, the chief obstacles to displacement being the concave form of the palmar surface of the carpus and the resistance offered by the anterior annular ligament. In this case removal of the bone was the only possible way of restoring the function of the wrist, reduction such a long time after the injury being quite out of the question.

Birmingham.

PRESENTATIONS.—Dr. James W. Norris Mackay, of Elgin, has been presented by the members of the Northern Counties branch of the British Medical Association with his portrait (painted by Sir George Reid), in recognition of the "valuable, disinterested, and unremitting services rendered by him as secretary and treasurer of the branch since its inauguration in the year 1863."—Mr. S. Boake, L.K.Q.C.P., L.R.C.S. Irel., who has conducted, at Chard, classes in connexion with the St. John's Ambulance Association, has been the recipient of a gold pencil-case and an illuminated address from the members of the classes as a tribute of their esteem.

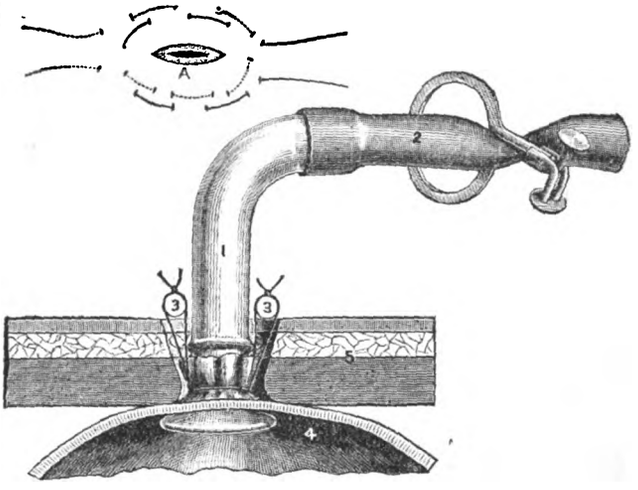
ROYAL INFIRMARY, LIVERPOOL.



A CASE OF PERFORATED GASTRIC ULCER; LAPAROTOMY; GASTROSTOMY; RECOVERY.[1]

(Under the care of Mr. F. T. PAUL.)

IT is well known to the readers of THE LANCET that we have constantly urged the publication of cases in which operation for perforating gastric ulcer has been performed, whether successful or not, and have done our best to spread a knowledge of the results obtained by different surgeons under the many and varied circumstances amid which cases have presented themselves for relief. There is probably no class of case which is calculated to cause greater anxiety to the medical attendant than one of this nature. Any additional success attained, any fresh suggestion of value in the treatment such as that made by Mr. Paul, may induce those in responsibility to recognise that not to recommend operation is to deprive the patient of a very good chance (and usually the only one) of recovery. The case of successful operation by Mr. Maurice, referred to by Mr. Paul, was published in THE LANCET. We have also given an abstract of a paper by Mr. Warrington Haward,[2] in which he described the case of a woman aged twenty-six who had been under his care, and on whom he had operated. As excision of the ulcer was not possible he had sutured its edges to the wound. The patient died from abscess of the lung six weeks after the operation.

About 1 A.M. on Dec. 13th, 1894, Mr. Paul was requested by Dr. Sidney Palmer to see with him a woman in whom he suspected that a gastric ulcer had recently perforated. The patient was thirty-one years of age, married, and a sufferer for years from dyspeptic symptoms. Six months previously the pain had become worse after food, so that she frequently induced vomiting to obtain temporary relief. The vomited matter was often dark brown and sometimes nearly black. Notwithstanding her constant pain and the advice of her medical attendant, she was far from careful in her diet, and on the night of Dec. 12th had a cold meat supper. This was shortly followed by the usual pain and vomiting, upon which there immediately supervened the most violent and agonising pain in the upper part of the abdomen. Her friends gave her a teaspoonful of brandy and applied hot fomentations, but without relief. Dr. Palmer was sent for. He found her in a condition of profound collapse and still suffering intense pain, so he injected morphia and took means to encourage reaction. About midnight the patient was beginning to get warm again, and the pulse to regain a little vigour. Mr. Paul was consulted as to the desirability of attempting relief by operation. On his arrival reaction was still further established. The skin was fairly warm, the pulse 130, the pain still severe, and the abdomen as rigid as a board from muscular contraction. The diagnosis seemed to be unquestionably correct, and there was no hesitation in advising the patient to submit to an operation. Unfortunately it was not convenient that it should be done where she was staying, so she was removed to the Royal Infirmary, Liverpool, and left in charge of the house surgeon, Dr. J. P. Nixon, with instructions to telephone as soon as she had fully recovered from the collapse, which of course had been somewhat deepened by the necessity of removing her. Mr. Paul went to the hospital on receipt of the message and commenced to operate at 7 o'clock, which was nine hours after the first onset of the symptoms. An incision was made four inches in length between the ensiform cartilage and the umbilicus. As soon as the peritoneal cavity was opened sour-smelling gas and greenish liquid escaped, and the neighbouring viscera showed signs of commencing peritonitis. The ulcer, though in a most awkward position, was easily found on account of its very large, hard, and thick base, which made it feel like a malignant infiltration. It was placed at the cardiac end of the lesser curvature, and it required some tension to keep it in view, even although the left rectus muscle was cut across to the margin of the costal cartilages. The rent was transverse and measured about half an inch in length. Excision of the ulcer was out of the question, and so awkwardly placed was the orifice that it appeared doubtful if it would be possible to close it with sutures. However, with small curved sewing-needles held in dressing forceps and armed with fine green catgut Mr. Paul was able to make some sort of a closure, over which he drew and stitched a tag of fatty omentum. But the coats of the stomach were so friable, and the position of the orifice so difficult to get at, that he did not consider the closure trustworthy. The front end looked pretty well, but at the back, where it was out of sight, the condition of the wound was very doubtful, whilst very little reliance could be placed on the sutures, even where satisfactorily tied, on account of the extreme friability of the tissues. It seemed that the first accumulation of either gas or fluid in the stomach would find a ready exit through the stitches, and therefore it was determined to drain the stomach by introducing a glass tube as recommended for gastrostomy and shown in the accompanying engraving. This is very easy to accomplish, and apparently is not a source of danger, but

GASTROSTOMY IN ONE STAGE.

it remains for time and experience to approve or condemn such a proceeding. Stomach drainage was employed here because Mr. Paul believed that the ulcer would certainly leak again unless placed under the most favourable conditions, and because it is a known fact that this secondary leakage is one of the prominent causes of failure in otherwise hopeful cases. The glass gastrostomy tube was fitted with a short piece of rubber tubing, which was closed for the present. Next the peritoneal cavity was well washed out with simple warm water, and the wound closed without drainage by passing fishing-gut sutures through all layers of the abdominal wall. On taking the patient back to the ward the stomach-tube was allowed to discharge in a jaconet bag containing antiseptic wool. She was kept warm and a brandy enema given. At first there was some abdominal pain, but it was not very severe. She felt sick and twice brought up a mouthful of brownish fluid. Copious vomiting was probably impossible with an open tube in the stomach. Thirst was avoided by frequent sips of warm water in which small doses of salol were occasionally given. For the first few days there was no great cause for anxiety. The temperature ranged between 98° and 100° F., and with the help of a little morphia she slept sufficiently and suffered but little pain. The pulse came down to 100. The urine was drawn off by catheter, and nutrient enemata were given every three hours. On Dec. 16th, the fourth day after the operation, stomach feeding was attempted by giving a little meat essence, but it had to be discontinued

on the 17th on account of fresh hæmorrhage from the ulcer, which continued on the 18th and 19th, and was unfortunately followed by a severe diarrhœa, which so reduced the patient that stomach alimentation became imperative. She was consequently fed on the 20th with prepared peptonised milk, and her condition began to improve. From this time there was no further cause for grave anxiety, and the rectal feeding, though not entirely discontinued, was no longer relied on. The sweetness of the peptonised milk caused her to turn against it in a few days, and the foods which proved the most successful were soup made from beef with vegetables in a muslin bag, and to which raw meat juice was subsequently added, and raw scraped-meat sandwiches. The latter caused neither pain nor sickness, and she improved rapidly on them. Fresh milk was disastrous in any form; even when partially peptonised it caused vomiting and a return of the hæmatemesis. The necessity for so much care in the feeding was that, apart from the operation and after the patient had recovered from it, the case was still a very bad one of gastric ulcer with advanced chlorosis and loud hæmic bruits and possibly mitral disease, for she had had three bad attacks of acute rheumatism. The history of the gastrostomy tube is as follows. During the 13th and 14th the discharge was slight. From the 15th to the 27th it was copious, but none escaped beside the tube, even although the ligatures came away on the 22nd. On the 27th the tube was removed, but with so much difficulty that it was decided not to use such a trumpet-shaped end in future cases, unless it was intended that the tube should remain in permanently. For a few days the discharge continued free at intervals, then diminished, and at the end of a fortnight the opening had closed. On careful diet the patient continued to improve. In the middle of January, 1895, she was allowed to get up, and at the end of the month she was discharged in a perfectly satisfactory condition of health.

Remarks by Mr. PAUL.—The cases which have been reported since Mr. Pearce Gould opened a discussion on this subject at the Bristol meeting of the British Medical Association all tend to confirm the views he expressed, both as to the causes of failure and the best means to attain success. The former may shortly be stated as (1) collapse; (2) imperfect cleansing of the peritoneum; and (3) further leakage of stomach contents. There is a general agreement as to the best way of dealing with the first two difficulties. Fatal collapse is to be avoided by operating at the right time—that is, during the stage of reaction and before peritonitis has fully developed. For this the surgeon must depend chiefly upon the promptness of his medical *confrères*, and also by making his operation as short and simple as is consistent with the object in view. The peritoneum is, I think, best cleansed by thorough flushing with simple hot water at a temperature of about 100°, and if boiling the water limits the supply or causes a moment's delay it is far better to use it unboiled. What are the few germs in the water to the myriads already in the peritoneal cavity, a proportion only of which can be washed out? Peritoneal drainage is better not resorted to, except in those cases where peritonitis is fully established, and most of these will end fatally any way. The third cause of failure—further leakage—is generally due to the inaccessibility of the ulcer, and the best means to be taken to avoid it have not yet been agreed upon. When the orifice can only be imperfectly closed it seems to me that it may prove wise to drain the stomach by a temporary gastrostomy, as in the case just related. When it is quite inaccessible I think it might possibly be sutured through an incision in the anterior wall of the stomach. This sounds severe, but it is decidedly less so than excision of the ulcer, which has been done, and in experimentally performing gastro-enterostomy upon dogs through a similar incision it was found that the healing of the wound in the stomach was always very perfect. However, it is not every ulcer that could be got at even in this way, though I can imagine cases in which I would be willing to give it a trial. The readiest method of meeting the difficulty was adopted by Mr. Maurice of Reading when he introduced an indiarubber tube into the stomach through the perforation and packed it round with gauze. In so doing I suppose one would probably frequently pave the way for future difficulties, but when the patient is too collapsed to permit of a more prolonged operation it seems to be the best and, indeed, the only reasonable method to adopt. I cannot think that washing out the stomach is generally a desirable proceeding. It prolongs the operation and must tend to increase the size of the perforation; moreover, if the sutures have any holding power at all they will outlast the time that the contents can remain in the stomach. Excision of the ulcer gains no support from the cases recorded by English surgeons, and if simple suture is sufficient, as has been amply proved, the much more severe operation of excision ought to be abandoned. The impression given to me by the case recorded above is that when taken at the right time, in a fairly good subject and with an accessible ulcer, laparotomy for perforated gastric ulcer will be a very successful operation; and the only reason why there are so few recoveries reported up to the present is that the medical world has not yet fully recognised that success depends mainly upon early operation. In conclusion, I would like to call attention to a point in the etiology of these gastric ulcers insisted on by my friend Dr. William Williams of Liverpool. He believes that the original cause is in many cases to be traced to the use of corsets. I am strongly of opinion that he is right, and have on more than one occasion confiscated my patients' stays and replaced them with the knitted woollen article with shoulder straps, which may be obtained from the sellers of Jaeger clothing. It contains a few "bones," but cannot be laced, and is, therefore, free from the worst defects of this pernicious article of female dress. Several of the so-called Jaeger stays are as harmful as any others, being, indeed, nothing but the vicious Parisian corset dressed up in Jaeger material.[4]

Medical Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

On Some Difficulties in the Use of the Curette.—Exhibition of Specimens.

A MEETING of this society was held on June 13th, Dr. CLEMENT GODSON, President, being in the chair.

Dr. MACPHERSON LAWRIE showed three specimens:—1. Removal of Suppurating Ovarian Tumour with Purulent Peritonitis and Adhesions. 2. Fibroma of the Uterus removed by Enucleation. 3. Total Extirpation of the Uterus and Ovaries for Prolapse. The patient, aged thirty, single, was confined of a child five years ago. Later she suffered from "bearing down" and hæmorrhage. When seen the uterus was prolapsed. An attempt was made to retain it in position with pessaries, but ineffectually, and it was decided to remove the uterus and appendages. Later she suffered from rectocele, which was cured by a plastic operation.—The PRESIDENT questioned the advisability of removing the uterus and ovaries for prolapse in a woman aged thirty.—Dr. ROUTH took exception both to the removal of the uterus, the prolapse of which might have been treated by some less radical method, and also to the removal of the ovaries. There was very little likelihood of menstruation persisting after hysterectomy; and the presence of the ovaries helped to retain the womanly characteristics.

Mr. CHRISTOPHER MARTIN showed two Uteri removed by Total Extirpation, after removal of the appendages two years previously, in the first case for double pyosalpinx, and in the second for double cystic disease. Menstruation persisted, in the first case very profusely, and in the second with great pain. Other means having failed, the uterus was removed. It was found that a piece of ovary had been left behind in the first case, and in the second part of the tubes, whilst the anterior wall of the uterus in this case contained a myoma. Mr. Martin attributed the persistence of menstruation to the fact that the menstrual nerves had been left intact.—Dr. LEITH NAPIER observed that the thickness of the uterine wall in the second case was suggestive of fibrosis, which often caused a continuance of hæmorrhage, even after removal of the ovaries.—Mr. TAYLOR (Birmingham) said that these were examples of a class of case in which hysterectomy had an important place, contrasting in this respect with Dr. Lawrie's case, in which the procedure was open to criticism.

Mr. TENISON COLLINS (Cardiff) showed an Impacted Ovarian Cyst which simulated a Myoma of the Uterus.

Dr. FANCOURT BARNES read a paper on Some Difficulties in the Use of the Curette. Curetting, he said, though a simple procedure, was not devoid of risk; it should, therefore, be undertaken with care. The first step was dilatation, which should be sufficient to admit the passage of

[4] The patient has gained 23 lb. in weight since the healing of the ulcer and the adoption of a "rational" corset.

Digitized by Google

the index finger. There were two methods of dilatation. The rapid method was by the use of Hegar's or other dilators; at the best it was a somewhat rough procedure, involving tearing and bruising of the cervix. He therefore preferred, as a rule, the gradual method, which was done by means of tents. They were safer and produced greater dilatation. Laminaria tents were the best, as the salts with which they were impregnated rendered them aseptic, and even antiseptic. They should be four inches long. Spoon tents were to be condemned. Under an anæsthetic the curetting was next proceeded with; a sharp curette or spoon might be used, or the dull wire curette or finger nail. The immediate risks were perforation of the uterus and hæmorrhage; later, atresia of the canal and pelvic inflammation. The two principal conditions calling for the use of the curette were chronic endometritis and retained products of conception. Cases were then related illustrating these conditions. In conclusion, the following questions were submitted for discussion: (1) What are the symptoms which point to the clear necessity of curetting the uterus? (2) which is the safest and most natural method of dilating the uterus? (3) should the curette be used in cancer of the uterus, more especially when the growth is at the fundus? (4) is it advisable to resort to the use of the curette for diagnosis? (5) is it possible to establish a satisfactory system of drainage of the uterine cavity after curetting?—The PRESIDENT, in thanking Dr. Fancourt Barnes for his paper, said he believed it was the first time the subject had been brought before the society. As curetting was a popular operation, it was advisable that the selection of suitable cases and the best method of its performance should be discussed. Whilst many operations rose for a time into prominence and then lapsed, he thought it unlikely that this one would fall into disuse because the resulting benefits were often strikingly evident.—Dr. MACPHERSON LAWRIE had done many curettings, but felt a certain anxiety about every case; yet no operation gave more satisfactory results. He used laminaria tents and a sharp curette; the cavity was then flushed with boiled water. Complete rest was required for some days after.—Surgeon-General HARVEY had operated in India both on Europeans and on natives, and had not found an anæsthetic necessary. He agreed with Dr. Barnes that sponge tents should be abolished. Even laminaria tents were not always satisfactory, for sometimes they expanded in an hour-glass fashion and their extraction was then difficult.—Professor JAPP SINCLAIR had also not found chloroform necessary; he gave a hypodermic injection of morphia an hour before the operation, and an alcoholic stimulant half an hour before. He had never seen any bad symptoms follow curetting, nor need there be any if care was used. Tents were the best dilators; it did not matter much how long they were left in. It was seldom necessary to introduce a finger, but when desired Hegar's dilators could be used, up to No. 12. The curette was valuable for diagnosis of cancer of the body, whilst in cases of suspected cancer of the cervix if a sharp curette were drawn across the diseased part, if it brought away tissue, the disease was cancer; if not, it was erosion. He believed this sign to be pathognomonic.—Dr. GREIG SMITH doubted the value of the sign given by Professor Sinclair in his last remarks. In his experience a sharp curette applied to an erosion would certainly bring away tissue. He usually neither dilated nor gave an anæsthetic; by pulling the uterine canal straight by means of a vulsellum on the posterior lip any moderate-sized curette could be introduced.—Mr. CHRISTOPHER MARTIN said there was one condition which had not been referred to, but which was capable of causing serious trouble after curetting—viz., slight disease of the appendages. In America curetting was done for this very condition, but he did not think it safe. A careful examination of the appendages should therefore always be made before curetting. In Birmingham they always gave an anæsthetic and used metallic dilators; a sharp curette was used, after which the cavity was swabbed out with iodised phenol and packed with iodoform gauze. He felt sure it was generally better to use an anæsthetic.

The discussion was then adjourned to the next meeting.

SUCCESSFUL VACCINATION. — Mr. T. Davies, public vaccinator for the suburban district of the Whittlesea union, has been awarded for the second time in succession the full amount of the Government grant for efficient vaccination.

Reviews and Notices of Books.

Diseases of the Ear. By A. MARMADUKE SHEILD, M.B. Cantab., F.R.C.S. Eng. Cassell and Co. 1895.

MR. SHEILD'S excellent little work on Diseases of the Ear is a vindication of the fitness of a surgeon on the general staff of a hospital to manage with success the aural department in conjunction with it. The pages he has written afford a clear demonstration of the methods of treating aural disease in accordance with the established principles of general surgery. He views the subject from no cramped and narrow standpoint, but brings ably to bear the experiences gained in the treatment of disease in other regions of the body. The divergencies from accepted traditions are not a few, but Mr. Sheild's defence of them is sustained by copious illustration from his case-books. The necessity of a sound knowledge of the principles of general medicine and surgery is his watchword throughout. The usual lengthy chapters on the anatomy and physiology of the ear are replaced by a brief and readable "sketch" in which the main facts are concisely summarised; the condensation has not been gained at the expense of accuracy, though on page 14 the statement that "the distance of the [mastoid] antrum from the lateral sinus is three to six *inches*" is clearly a misprint. In the chapter on examination for diagnostic purposes emphasis is rightly laid on the superiority of the watch and conversation tests over other more subtle methods; but the description of the use of the tuning-fork is for no very obvious reason divided into two portions separated by some pages dealing with other matters.

The diseases of the auricle and external auditory canal are fully described, and Mr. Sheild takes up a firm position with reference to the effects of impacted cerumen, holding that when perforation of the tympanic membrane coexists the latter is due to pre-existing disease of the membrane or of the middle ear. This view, though running counter to the commonly received opinion, is certainly supported by the previous history of many of these cases.

The subject of aural exostoses receives full attention, and the value of the electro-motor for drilling and removing these growths is pointed out. The remarks on impacted foreign body are very practical, but the author states that he has had no experience of the use of the galvano-cautery, which has proved most useful in the hands of others when dealing with these cases. The chapters on the inflammatory affections of the middle ear are well written, and especially that dealing with chronic otitis media associated with perforation. The cerebral complications of ear disease are the subject of a brief but clear sketch, though it would have been well if more details had been given concerning the operative treatment of these cases. The operation preferred for adenoids is that performed by means of the steel nail, the patient being placed on his side, with the head over the edge of the table. Mr. Sheild insists strongly on the importance of after-treatment in these cases, relying chiefly on the application of astringents to the naso-pharynx and a methodical use of the Politzer bag. The chapter on nerve deafness is good, and an intelligent account is given of the methods of detection of malingering. At the end of the book are arranged some useful prescriptions for local and general medication. The little work is neatly got up and is freely illustrated. It may be regarded as a safe guide to the treatment of diseases of the ear.

Atlas of Clinical Medicine. By BYROM BRAMWELL, M.D. Edin. Vol. III., Parts I. and II. Edinburgh: T. and A. Constable. 1894 and 1895.

THE bulk of the first of these two parts of Dr. Byrom Bramwell's admirable Atlas consists of the substance of

Digitized by Google

an address to the Dermatological Society of Great Britain and Ireland delivered about a year ago. It deals with the subject of the thyroid treatment of skin diseases—a subject which the author has taken up with enthusiasm and prosecuted with assiduity. The cases, which are here given in full detail, and are abundantly illustrated by a large series of photo-lithographs, seem to speak strongly in favour of the plan; but it may be pointed out that the majority of them were cases of psoriasis, and that few skin affections are more amenable to treatment, or perhaps we should say tend so frequently towards temporary alleviation under the influence of rest, diet, and local applications. Nevertheless, the results recorded by Dr. Bramwell, not only in psoriasis, but in lupus and some other skin diseases, are so uniformly successful, and, as the photographs show, so complete in result, that scepticism is disarmed, and we are forced to admit the beneficial influence of the administration of thyroid extracts (local treatment not having been used), although it may be difficult to explain the precise *modus operandi* of the remedy. It might be thought that in cutaneous affections the determination of the efficacy of any particular line of treatment could be easily determined, but it must not be forgotten that even here, as in other therapeutic trials, much depends upon the attitude of the observer. Thyroid therapeutics in skin disease have been found wanting by other observers; but Dr. Bramwell hints that in many cases want of faith in the efficacy of the remedy may in such instances have led to a too early abandonment of the trials or a too timid exhibition of the drug. At the same time, the remedy is one which does require caution in administration, and whether, after all, in such an affection as psoriasis it is worth while to substitute this powerful measure for treatment of a less heroic kind must be left to dermatologists to determine. Besides this exposition the first part of this third volume of the Atlas contains an excellent account of acute anterior poliomyelitis (infantile paralysis) and the record of an interesting case of malignant disease. The second part, just issued, also enters fully into progressive muscular atrophy and the muscular dystrophies in general. These conditions are admirably adapted for pictorial representation, as may be seen in Professor Curschmann's recent "Klinische Abbildungen." Dr. Bramwell gives several plates to illustrate this part of the text; the issue also including descriptions and drawings of hereditary syphilis, ichthyosis, and an excellent coloured portrait of cyanosis. The thoroughness with which the author treats his subjects and the high standard of excellence maintained in this Atlas render it one of the most valuable publications of the day, and testify to the energy and clinical enthusiasm which have produced it.

The Natural History of Plants. By ANTON KERNER. Translated and edited by F. W. OLIVER, M.A., D.Sc., with the assistance of MARIAN BUSK, B.Sc., and MARY EWART, B.Sc. Parts 7 to 11. London, Glasgow, and Edinburgh: Blackie and Son. 1895.

WITH the seventh part of the serial issue of the English edition of the work of the Vienna professor of botany the first volume was completed. That portion of the book dealt with questions of morphology in a manner at once attractive and profound, for the work, whilst being strictly scientific, is written in so lucid and charming a style that its popularity on the Continent is not surprising. The present translation enables the botanical student in this country to share in the rich storehouse of instructive facts that are arranged so plentifully in these pages. There is a masterly freshness and originality of treatment that show that the author has attained to the most intimate familiarity with the conditions of plant life and the innumerable adaptations of structure to environment that the plant exhibits. No less interesting are the sections of the second volume which have so far been published; indeed, in many particulars they open up questions of surpassing interest which have engaged the attention of the greatest masters in science, for they deal with the subject of the reproduction of plants, which is introduced by descriptions of the asexual modes as seen in the spores and thallidia of cryptogams and the buds on stems and roots of higher plants. But the main share in perpetuating the cycle of vegetable life on the globe is effected by fertilisation and fruit formation, and it is in the study of the various means adapted to this end that so much has been learnt by the patient researches of botanists. This subject is introduced by the description of fruits and fruit formation in cryptogams and phanerogams, the fruit being defined as "the product of fertilisation, and at the same time constituting the first step towards the renewal of the fertilised plant." It is shown how cryptogams—e.g., ferns and mosses—are fertilised under water, and most phanerogams in the air, hence it is that most of the latter are provided with blossoms which are lacking to the former. The various means for the preparation, storage, and distribution of pollen, the part played in fertilisation by wind and by insects, which go far to explain the diversity and beauty of the floral world—these and a multitude of cognate questions are handled by the author in a most fascinating way. We can well imagine how the perusal of even a few pages of such a book as this would arouse an enthusiasm for botanical study in the most indifferent, and now that the season is at hand when the material for this study abounds in every field and hedgerow we can recommend no sounder guide, at once instructive and alluring, than this work, which we think will do not a little to revive an interest in botany beyond the circle of the specialist. Many a hard-working practitioner of medicine has in times past gained wholesome recreation and renewed his energies by devoting his spare moments to the contemplation and study of the natural phenomena that surround him in his daily walks, and not a few members of our profession have aided considerably the advance of natural knowledge. And, although the mass of other technical subjects may have crowded botany out of the ordinary curriculum of medical study, we do not doubt that its pursuit will still be taken up from a pure love of nature. To such we heartily commend this work, the great feature of which is that it has imparted a fresh interest in a subject too long under the thraldom of a rigid system of classification. Botany, or, as the title of this book gives it, "The Natural History of Plants," has gained immeasurably in interest by the study of plant life as distinct from plant form.

LIBRARY TABLE.

A Handbook of Pathological Anatomy: Based upon the Catalogue of the Pathological Museum, University College, Liverpool. By RUBERT BOYCE, M.B., George Holt Professor of Pathology, Pathological Superintendent, Royal Infirmary, Consulting Pathologist, Royal Southern Hospital; and J. HILL ABRAM, M.D., M.R.C.P., Assistant to the Professor of Pathology, Assistant Physician, Stanley Hospital, Pathologist, Royal Infirmary. Liverpool: T. Dobb and Co. 1895.—This volume, consisting of about 500 pages, is an elementary treatise on selected subjects in pathological anatomy, combined with references to, and short notices of, illustrative museum specimens. The general plan is excellent and has been well carried out. Even without inspection of the specimens, anyone having a moderate acquaintance with pathology is likely to profit by a perusal of the full and clear account of the various lesions and abnormalities described. Beginners, however, would probably find one of the systematic elementary manuals more useful,

Digitized by Google

Access to the specimens being presupposed, illustrations are naturally not supplied in the text, and the references to minute structure are comparatively few. The sections on the abdominal and pelvic viscera and on the bones and joints are especially copious and worthy of attention.

St. John Ambulance Association. Hints and Helps for Home Nursing and Hygiene. By E. MACDOWEL COSGRAVE, B.A., M.D., Ch M., F.R C.P.Irel. With a Chapter on the Application of the Roller Bandage by R. J. COLLIE, M.D. Ninetieth Thousand. London: St. John's Gate, Clerkenwell. 1895.—This is the authorised text-book on nursing issued by the St. John Ambulance Association, and is arranged according to the syllabus of the second (or nursing) course of lectures. It contains a large amount of useful information on the general management of a sick-room, as well as on dietary and the use of medicines and other remedies. There is a short special chapter on the nursing of sick children. In the chapter on baths, those from 110° to 120° F. are described as "very hot." This is strictly correct, and the author might have added that no one ought to be suddenly immersed in water even at 106°. For very hot baths the temperature should at first be about 103°, from which it may be raised by successive additions of hot water to about 110°, and the attendants should keep in mind that faintness may result.

Venice ("Story of the Nations" Series). By ALETHEA WIEL, author of "Vittoria Colonna" &c. London: Fisher Unwin. 1894.—Venice, or rather the Venetian Republic, occupies too conspicuous a place in the history of medicine to make its political and social life other than profoundly interesting to physicians and surgeons. To know and to appreciate under what vicissitudes the great school of Padua—the *alma mater*, among others, of William Harvey—rose and fell and rose again must be matter of more than mere "intelligent curiosity" to the profession. For such knowledge and for the intellectual "coign of vantage" it gives Madame Wiel provides admirably in the flowing, picturesque, and exceptionally sound narrative conveyed in this volume. Amid what environments Luigi Cornaro practised what he preached towards attaining his hundredth year, or Geronimo Mercuriali composed his masterworks on the lines of that Hippocrates whom he so usefully edited, may be pleasantly learned from her animated and impressive pages. The book is one of the best of the series to which it belongs, a recommendation to which no student of contemporary literature can fail to attach its true value.

MAGAZINES FOR JULY.

The Practitioner.—This estimable little monthly keeps up its usual high standard of excellence. In one of the annotations on events of the past month is a reference to Sir Richard Webster's Insurance of Children Bill, in which the writer regrets its withdrawal—a regret which we are sure all our readers will share. If that mysterious entity "the feeling of the country" is not ready to accept Sir Richard Webster's Bill, it surely would accept one for forbidding the insurance of illegitimate children; for it is to everyone's interest that these should be got out of the way, and every medical man whose practice lies among a certain class knows perfectly well that the "removal" is effected and how it is done. Dr. Stephen Mackenzie contributes an interesting and useful paper upon a very distressing and common condition—namely, Flatulence. Mr. Victor Horsley gives five cases of Operation in Leontiasis Ossium, and Mr. Walter Jessop writes on Ocular Headache. Dr. Fletcher Beach continues his paper upon Feeble-minded Children, and there is a good article upon Waters and Baths for the Gouty.

Chapman's Magazine.—When a magazine starts as well as Chapman's did there is always an idea that the first standard of excellence will not be kept up, but of this there is no sign. Mrs. Andrew Dean contributes a clever sketch of some singularly disagreeable people, and Mr. Crockett describes a vision of fiends equal to that appalling one of the pig demons under the gallows reported by Dr. F. G. Lee, and they were the *premier cru* of bogeydom. However, no doubt the visions were due in both cases to some error of refraction accentuated by dyspepsia. Mr. Bret Harte's serial gives a life-like picture of "road agents" and their doings, and Miss Violet Hunt continues to evolve in her admirable manner the character and little ways of Mrs. Munday, as fascinating a woman as Becky Sharpe. We are sorry to see there is one blemish in the shape of an in-set advertisement.

The Contemporary Review.—Professor Lombroso writes on Atavism and Evolution, showing how a return to primitive ways may be coexistent with the most modern developments. Mr. Herbert Spencer contributes a paper on Dancers and Musicians, where, in speaking of religious dances, he quotes an instance of Christian religious dancing "in a remote region" among the Pueblos. He might have quoted an instance much nearer home—namely, the solemn dance before the high altar at Seville (we think the town is) on the festival of Corpus Christi. Mr. Charles Roberts contributes an interesting paper on the Physiology of Recreation, and Mr. A. W. Hutton writes an earnest plea for a national opera house. This last, though an excellent idea, we fear, would fail if not very carefully organised. The Albert Hall, the only musical institution in any way connected with the State that we have, is a disastrous failure from a musical point of view, excepting as regards the Royal Choral Society.

The Scientific Roll and Magazine of Systematised Notes: Climate—Baric Condition Conducted by ALEXANDER RAMSAY. Nos. 1 to 6. London: The Castle Printing and Publishing Company, Elephant-road, Elephant and Castle. 1894.—Temperature, rainfall, sunshine, and the prevailing directions of the wind are the principal atmospheric conditions taken into account in the investigation of existing diseases or in the selection of health resorts. To an important section of the community, however, sea voyagers, and the shipping interest in particular, the barometric movements are of at least equal consequence, and it is this branch of meteorology which Mr. Ramsay has taken up in the volume now issued in serial form. In subsequent volumes he contemplates dealing with the questions of carbonic acid and chemical rays, dust haze, electrical condition, &c. In an essay introductory to the present work he discusses the cause of the rise and fall of the barometer, arguing that it cannot be directly accounted for by variations in temperature and aqueous vapour, but suggesting that when currents of air are set up by differences of temperature and dew-point they meet with unequal resistance. In consequence of its elasticity the air may be held back when flowing over a surface presenting more than usual friction, and, at the same time, will flow rapidly over the smoother tracts. More air, therefore, flows in one direction than in another, and in proportion as the weights of the incoming and outgoing columns of air differ so the barometer rises and falls. He then gives a *résumé* of the barometric observations of various eminent meteorologists and their comments thereon as recorded up to the year 1845.

The *Twentieth Century* has an appreciative article by Karl Blind upon Jacob Moleschott, the eminent physiologist of Heidelberg. The article deals mostly with the political side of Moleschott's career, as might be expected from its author. Moleschott and his successor Huxley had many things in common, both as to their work and the way it was received,

Digitized by Google

and both, to use Moleschott's words, tried "to describe in clear, easily understandable language the incessant course of the elements throughout the animal and vegetable world." There is an interesting paper on the Dawn of the Railway Era. The necessary characteristics for an engine-driver in 1841 were "that he should not be deaf, shortsighted, or subject to fits, and should be of affable manners, so that in the event of an accident he might prevent dissatisfaction among the passengers by his intelligent conversation." Even though testing for colour blindness and acuteness of vision is not made compulsory by the Board of Trade, it must be admitted that the standard of qualification for driving an engine has been raised since 1841. There is an essay by George Morley on George Eliot's country, and Mr. William Graham tells the story of the Byron separation.

The Westminster Review.—The first article in this magazine has a melancholy interest at the present time. Apart from the metaphysical subjects of which it treats, it deals with the late Professor Huxley's views on Hume and Berkeley written by a "humble disciple," Mr. G. G. Greenwood. The paper entitled the "Mystery of the Pacific" treats of Easter Island and the Atlantic tradition. An Irish Protestant has a really admirable paper on Education in Ireland, showing the manifest superiority of Roman Catholic education in Ireland. Anyone who has read the Stonyhurst manuals will agree with the writer that the Jesuits are admirable teachers.

The Humanitarian.—There is an interesting article by Mr. R. H. Sherard, "An Interview with Daudet," who mentions amongst other matters the great increase of drunkenness in France owing to the ruin of the vineyards, so that instead of the light wholesome natural wines, the people are compelled to use artificial wines, absinthe, &c. The Rev. W. J. Wood has a sensible article on the purity question and the avoidance of syphilis.

Analytical Records
FROM
THE LANCET LABORATORY.

"LIQUEUR ADVOCAAT."

(SIMUNDT, SLATER, AND CO., 2, GUILDHALL-CHAMBERS, BASINGHALL-STREET, E.C.)

ALTHOUGH only recently introduced into this country by the above firm, who are the original manufacturers, this "liqueur" appears to be well known on the Continent. Its formula is certainly not new, since it is composed of yelks of eggs with a blending of certain choice liqueurs and mature brandies. In the present preparation, however, the combination of these ingredients has been very satisfactorily effected. The taste is delicately and agreeably aromatic and its consistence uniform. Such a mixture is, of course, well known as a vigorous restorative, and scientifically it is a distinct advance on liqueurs, which are mostly and simply composed of syrup, spirit, and flavouring.

VINOLIA SOAPS.

(BLONDEAU ET CIE: LONDON DEPÔT, RYLAND-ROAD, N.W.)

No less than twelve varieties of this well-known soap have been submitted to us for examination, and it is sufficient for us to record, as affording evidence of their economic value and admirably balanced composition, that in the analyses we made the moisture was found to range from, in one instance, as low as 4·66 per cent. to 7·44 per cent., the mean of the total number examined being 6·20 per cent.; alkali in combination with fat ranged from 8·23 per cent. to 10·60 per cent., the mean of the total examined being 9·70 per cent. soda (Na_2O); free alkali was not found in any single instance. These, as well as other satisfactory indications obtained on testing—as, for instance, the freedom from foreign substances sometimes, but unjustifiably, used in the preparation of soaps—are such as to satisfy both requirements of a soap intended for toilet purposes—i.e., being emollient as well as cleansing. The delicate fragrance of these soaps enhances their attractiveness.

ANTISEPTIC MOUTH PEARLS.

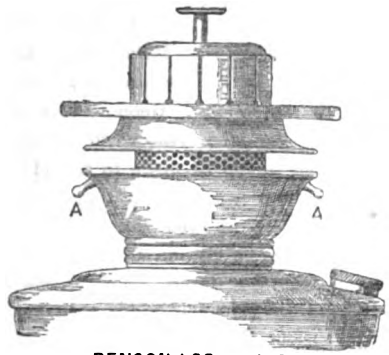
(S. RADLAUER'S KRONEN-APOTHEKE, 160, FRIEDRICHSSTRASSE, BERLIN, W.)

These pills, containing thymol, saccharin, menthol, eucalyptol, vanillin, and volatile oil, afford a convenient, portable, and effective form of mouth wash. Though, as will be seen from their composition, they must possess very distinct antiseptic properties, yet they are not likely to be injurious; in addition, their taste is agreeable rather than the contrary. They supply an important requisite.

DRY ANTI-DIPHTHERITIC SERUM.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, E.C.)

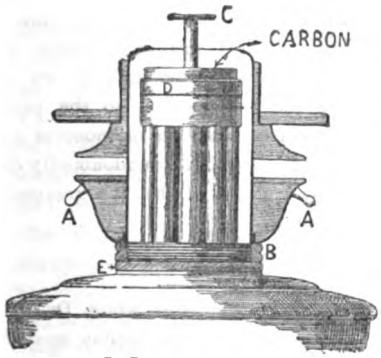
We have received from Messrs. Burroughs, Wellcome, and Co. a specimen of dry anti-diphtheritic serum in the form of fine golden scales, which they claim they were the first to prepare. The dried serum is freely soluble in about twice its volume of cold water. One gramme contained in a glass tube represents ten cubic centimetres of the normal liquid anti-diphtheritic serum, and it is stated that to obtain the full potency of carefully prepared liquid serum it is merely necessary to dissolve the contents of the tube in this quantity of cool but previously boiled water. We cannot speak here as to its therapeutic activity (which, however, is guaranteed by the makers), but the convenience of this preparation is obvious; while the fact that in the dry state the serum is permanent is a very important additional advantage. The sample is labeled with the date of preparation, the number of the horse from which the serum was derived, and the degree of immunity it possesses, all of which are attested by the signature of the medical director in charge of the biological laboratory.



New Inventions.

THE BENSON-LEE SAFETY LAMP CONSTRUCTED WITH CARBON BURNER.

IN seeking to overcome one objection it occasionally happens that more than one improvement is effected, and this would appear to be the case in regard to the Benson-Lee lamp. Primarily the object of the invention was probably only to improve upon the wick by substituting for the cotton wick a more or less solid wick of some porous and indestructible material, which would not require trimming or levelling or adjusting in any way. Not only have the inventors, we find, succeeded in the present instance in carrying this out, but by the introduction of a collar of gas carbon, which was subsequently chosen to replace the ordinary cotton wick, the burning of oil of comparatively low flashing-point, like the petroleum at present supplied for lighting purposes, is made quite safe, without its lighting efficiency being in the least degree affected. We find, for instance, that on tilting the lighted lamp through a right angle or by turning it completely upside down the light is immediately extinguished and not a drop of oil is spilt. It would appear, therefore, that the hard gas carbon wick affords an efficient barrier against the ignition of the oil in the reservoir, besides which, by means of an arrangement which allows air freely to play round the tubes containing the small cotton wicks supplying the carbon burner with oil, the latter is kept comparatively cool. As will be seen from the accompanying illustration, the wick is compound—that is, it consists first of a series of small cotton wicks enclosed in the small tubes comprising the centre column of the burner. These convey the oil to the carbon wick or burner, so that on its way it passes over a large cooling surface before it reaches the flame. The size



Digitized by Google

of the flame is not regulated by moving the wick up or down, but by controlling the air-supply, which enters just above the points A A, which are the knobs for screwing the lower cup, to which they are attached, right up to the top if necessary, and so stopping the air-supply altogether and extinguishing the flame. The lamp gives a white, steady, and brilliant flame, which never presents an unsightly or

BENSON-LEE LAMP

uneven appearance, because the wick always keeps the same level and never requires trimming. Apart from the very important advantage of the security which this device affords against explosion or ignition of the oil, it is obviously an improvement which those who know the inconvenience and trouble of keeping wicks constantly trimmed, and the nuisance caused by detached and half-consumed pieces of wick getting into the fittings, will thoroughly welcome. Indeed, it removes not a few of the strongest drawbacks to the system of lighting by oil; the wick cannot get out of

SECTION OF BURNER

order, objectionable smells are consequently avoided, while from the fact that it fits perfectly the burner tube it affords an effectual precaution against accidents arising either from the spilling of the oil or the ignition of the vapour in the reservoir. The "life" of the "carbons," which may easily be replaced, is said to be from two to four months. New carbons take some time before they give the maximum light, until, in fact, they are saturated with oil and the oil is travelling freely through them. Messrs. W. A. Benson and Co., 82, New Bond-street, are the makers.

ASEPTIC CATHETERS.

MESSRS. MAW, SON, AND THOMPSON have introduced at my suggestion an alteration in the manufacture of flexible catheters which I believe to be an improvement of considerable value. A great deal of attention has been paid to the outer surface of catheters, to the shape and position of the eye, to the neck, and to the end beyond the eye; the interior, the part that comes into closest contact with the urine, has not been touched. It is left rough, irregular and uneven, with in some instruments the fabric exposed so that the urine can cling to it and even soak into it. Proper cleansing without elaborate appliances and unlimited leisure is almost impossible. Anyone who will split open an old catheter, one that has been in use for some time, and will inspect the interior will see at once what I mean. The new ones that Messrs. Maw, Son, and Thompson have made for me are as highly polished and as finished upon the inner surface as they are upon the outer. They can be cleansed and rendered aseptic with the greatest ease. There is no need for any elaborate apparatus. If they are placed at once, after having been used, end upwards in a deep bottle filled with a solution of boracic acid, every trace of urine is expelled immediately and replaced by the antiseptic, and the instrument is fit for use again. It is not possible for an old man with enlargement of the prostate who has to pass an instrument many times in the twenty-four hours and often at night to cleanse an ordinary catheter effectually. With these there is no difficulty. They can be rendered aseptic at once and in a manner so simple that the most ignorant cannot make a mistake.

Wimpole-street, W. C. MANSELL MOULLIN.

SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual general meeting of this society was held at 429, Strand on June 28th.

Mr. Joseph Smith was elected President for the year, Mr. George Brown honorary treasurer, and Mr. W. G. Dickinson (Southfields, S.W.) hon. secretary.

The Secretary reported the correspondence between the committee of the society and the Home Office in connexion with the recent amendment of the by-laws of the College, the result of which met with the approval of the meeting.

The following resolution was proposed by Mr. Nelson Hardy, seconded by Dr. Thos. Morton, and carried unanimously: "That this meeting is of opinion that the time has come when active steps should be taken to secure for Members of the Royal College of Surgeons of England their due share in its management, in accordance with the request of nearly 5000 Members contained in the petition to the Privy Council in the year 1887."

The honorary secretary will be glad to receive the names of any Members of the College wishing to join the society. The annual subscription is 2*s.* 6*d.*

ROYAL MEDICAL BENEVOLENT COLLEGE.

THE foundation stone of the New Lower School will be laid by His Royal Highness the Prince of Wales, K.G., at 3 P.M., on Monday next, July 8th. Tickets of admission to witness the ceremony, which will be issued in priority of application, can be obtained by letter from the Secretary, at the Office, 37, Soho-square; or of the Bursar, at the College, Epsom. H.R.H. the Princess of Wales has graciously announced her intention of being present.

A special train will leave Victoria Station at 1 P.M., calling at Clapham Junction, Mitcham Junction, and Sutton Station, and leaving the Downs Station for the return journey about 5 P.M. Return tickets from London, which must be taken at Victoria Station, will be issued at three shillings. It is requested that those applying for tickets will give notice if they will travel by the special train. The return tickets will be available by the ordinary trains of the London, Brighton, and South Coast Railway at the Downs or Epsom Town Stations.

It is hoped that as many members of the profession as possible will attend the ceremony out of compliment to their Royal Highnesses the Prince and Princess of Wales, no less than out of a due sense of the excellent work that has been done by the authorities of the institution. And while writing of this work it will not be out of place to call attention to the fact that an election by the Council of the College to a scholarship, giving free education and maintenance at the School of St. Anne's Society will shortly take place. Candidates must be between the ages of seven and twelve, and must be necessitous orphan daughters of duly qualified medical men who have been for not less than five years in independent practice in England or Wales. Forms of application can be obtained at the office, and applications must reach the secretary not later than the morning of July 16th.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, JULY 6, 1895.

THE time is approaching when the claims of the Members of the Royal College of Surgeons of England to a share in the government of the institution must receive the careful consideration of the Council of the College. There can be very little doubt that there is among the Fellows of the College a growing feeling in favour of some concessions being made by the Council to its immense constituency of Members. Strange as it may seem to all who are acquainted with the elementary facts concerning the constitution of the College, we do not hesitate to assert that one of the main causes of denial of due recognition to the Members has been ignorance of the actual position of the Members of the College as an integral part of the "body politic and corporate of the said College." More than once have we heard Fellows of the College asseverating that the Members of the College have no more right to consideration than the Licentiates of other corporations—the Royal College of Physicians, for instance. When this ignorance is liable to be carried even into the council chamber of the College, how can it be expected that the claims of the Members can advance very speedily to a favourable solution? In the hope that this may meet the eye of Fellows who still entertain an erroneous view of the position of the Members in the constitution of the College we will quote a paragraph from the Charter of March 18th, 1852.

"Whereas the body politic and corporate of the said College at present consists of persons created Members of the said College by the said first-mentioned charter, or constituted such Members by letters testimonial under the common seal of the said College, of the respective qualifications of such persons to practise the art and science of surgery, and also of persons created Fellows of the said College under the provisions of our said letters patent, and elected and declared to be Fellows of the said College by one general diploma under the seal of the said College, enrolled in our High Court of Chancery, and also of other persons appointed under the powers of our said letters patent by the Council of the said College, to be Fellows of the said College by diplomas under the seal of the said College, and also of other persons who, after having attained the age of twenty-five years and complied with the rules and regulations directed by the bye-laws of the said College, and having passed a special examination by the examiners of the said College, have been admitted Fellows by diplomas under the seal of the said College." In short, "the body politic and corporate" of the Royal College of Surgeons of England consists of the Members of the College and the Fellows of the College. Licentiates of the other licensing corporations do not belong to the corporate bodies.

It is this fundamental fact that the Members of the College are a part of "the body politic and corporate" of the College that forms the basis of the claims of the Members to a share in the government of the institution. The claims are upheld by many considerations, amongst which the most cogent is that the College derives its main pecuniary support from the fees of candidates for the Membership, for those who do not admit that the maxim that taxation and representation should go together is applicable to the case of the Members must acknowledge that it would be for the good of the College that the Members of the College should be interested in its welfare and not alienated by exclusion and repression. Hence it is that many Fellows are, we have good reason to believe, anxious that some concessions should be made to the Members, and that, without derogation from the position of the Fellows, the Members should be allowed to participate in some degree in the Government of the College. The progress of these opinions amongst the Fellows of the College is specially gratifying to THE LANCET, which has from the earliest period upheld the claims of the Members as deserving of far more consideration than they have ever yet received, and at an early date we hope to recur to the subject, and to point out how the legitimate aspirations of the Members may be satisfied with advantage alike to the Members, the Fellows, and the Council. During the progress of an election of representatives of the Fellows to serve on the Council of the College it is almost impossible for those who sympathise with the Members in their desire for an adequate share in the management of the College with a view to increasing the influence of the institution to do much to advance the cause. Now, however, that the election is over we trust that the importance to the College and to the profession of uniting the whole constituency in harmonious relationship will receive the attention which it undoubtedly demands at the hands of all loyal scions of this the greatest of all our professional institutions.

THE subject-matter of the paper which Dr. THIN contributes to our columns to-day is a forcible reminder of the invaluable services which the microscope is rendering to medical science. He does well to place in the forefront the remarkable fact that the most striking discoveries which have been made by means of this instrument are those which have demonstrated the existence of parasitism as the etiological factor in important group of diseases. The three examples which he specially cites—tuberculosis, leprosy, and malaria—are in themselves accountable for so large an amount of disease and premature death that the discovery in them of the causal agent would alone make the latter half of the century memorable in the history of medicine. But when to those are added septic diseases, anthrax, glanders, actinomycosis, relapsing fever, diphtheria, and enteric fever, besides other affections in which the evidence of parasitism is less crucial, the additions made to knowledge and the gain in insight into the causes of disordered function during a comparatively brief period are so vast as to amount to the opening of an entirely new chapter in that history. The subject upon which Dr. THIN especially dwells is one of the most interesting and important of them all. For in the first place the class

Digitized by Google

of parasites which LAVERAN discovered in malaria is wholly different from that revealed in connexion with other diseases; and in the second place, the seat of operation of the invading host is quite special and peculiar. For the malaria parasite is of animal nature, belonging to the lowest forms of protozoal life, and its particular object of attack is the red corpuscle of the blood, the destruction of which goes far to account for the phenomena of malarial fevers and their sequelæ. Not that LAVERAN'S parasite stands alone amongst hæmatozoa, but rather that those other parasites which make the blood their habitat—e.g., the filaria sanguinis hominis—are quite different from the malaria organism in their action, just as they differ in their position in the zoological scale. Indeed, with the exception of this one, human hæmatozoa are not in the strict sense blood parasites. They inhabit the blood, and are conveyed in its stream or impart to it toxic properties; but they do not, as the malaria organism does, fasten themselves on the formed elements and live at their expense. Remarkable as this property may be, it has its counterpart in the lower animals, for parasites, very analogous in type and in mode of attack, have been discovered in the blood corpuscles of frogs and of certain reptiles and birds, and have been termed "drepanidia." The progress of research into the malaria organism, as sketched by Dr. THIN—and later carried on by GOLGI, MANNABERG, MARCHIAFAVA, BIGNAMI, and others,—has considerably extended our knowledge of the developmental changes of the parasite and of the various forms associated with different types of malarial fever. It has been shown that the character of the fever—the clinical type to which it conforms—is related to the length of time taken by the parasite to develop in the blood corpuscle, assimilate its colouring matter, and eventually break up into "spores" the dissemination of which coincides with each pyrexial paroxysm. Thus in the quartan type—as GOLGI showed—the parasite may be seen to grow within the blood corpuscle, and at the end of sixty hours, or twelve hours before the next attack, to almost entirely fill it; then it begins to subdivide, and in six hours more to get free from the investing sheath, the last relic of the destroyed corpuscle, and appears as a congeries of radial bodies ranged around a mass of pigment, the final separation into free "spores" occurring at the close of the apyrexial interval. The tertian parasite goes through its evolution in a proportionately shorter space of time—forty-eight hours—and the quotidian in only twenty-four. There are varieties of form as well as variations in the rate of growth, and a special form has been described as characterising the pernicious types of fever. It would be too much to say that all lacunæ in our knowledge of the life-history of these organisms have yet been filled; but it is at least surprising how much has been established, thanks to the patient work of microscopists. One great discovery yet remains to be made, and that is the demonstration of the parasite outside the body and the route whereby it gains access to the blood. We infer that it must be in soil or water, but its presence therein has not been proved. This link in the chain is also wanting in the case of the sporidia which have been alluded to as attacking the blood corpuscles of certain other vertebrates.

One great merit of Dr. THIN'S paper lies in the careful details he gives to enable others to detect these minute organisms in the blood of malarial subjects. Himself a skilled microscopist and fully aware of the importance of attention to the smallest detail in a research so delicate as this, he has placed it within the power of all engaged in the task of dealing with these formidable fevers to add largely to their diagnostic appliances. The carefully executed coloured drawing which accompanies his paper will be of further assistance as enabling such medical officers to recognise the characters of these organisms. He shows, too, that this microscopical work has a direct practical value, for when the diagnosis of the true nature of the attack of "fever" is thereby placed beyond dispute there can be no hesitation as to the course of treatment to be followed. Not the least interesting fruit of LAVERAN'S discovery has been the demonstration that the efficacy of quinine lies in its parasiticidal property. Thus does science give proof of the direct action of a remedy long known and prescribed on purely empirical grounds, whilst at the same time it demonstrates the limits within which such remedial action alone can operate.

IF charity ever should fail in reference to our voluntary hospitals it will be largely due to the faults of their administration, and especially to that of the out-patient department. We insert to-day an interesting letter from a clergyman on one crying evil of the out-patient system—the delay and detention of patients. Our columns, as is well known, are reserved chiefly for the use of members of our own profession; but this is a point and the present is a time at which the clergy have a good right to a special hearing. They have just been making a collection in their various churches, forgetting all distinctions of creed, and so supplying a much-appreciated contribution to the maintenance of our hospital system. "That other church—the hospital," was the eloquent and happy expression of a deep truth which we owe to one minister of the Gospel on the recent Hospital Sunday. We have much pleasure, therefore, in finding room for the letter of one of a class to whom our hospitals owe so much, and who, it will be admitted, owe much to our hospitals. A clergyman in one of our poorer parishes without facilities for securing the medical treatment of the poor whom he visits, and especially their admission, in urgent circumstances, to a hospital, would feel deprived of one of his chief pleasures. We recognise the force of the objection of our clerical correspondent to a system which "keeps many delicate invalids in the melancholy waiting-room for four, six, or even eight hours, waiting the convenience of physicians, surgeons, and apothecaries." We have no hesitation in admitting—indeed, we have often pointed out—that such a system "is a cause of intense mental, and not infrequently physical, suffering to the patients." The case is aggravated in those who have come a distance or have to give up a day's work to attend the hospital. Our correspondent thinks this evil so obvious and so great that he is at a loss to understand how it is allowed to go on without any efficient attempt to remedy it. He is so puzzled at the want of reform in this direction as to have come to rather an uncharitable theory for one of his

Digitized by Google

profession—namely, "that the physicians and surgeons are in league to resent the smallest interference," and that the governors or secretaries will not attend to details so minor in their estimation.

We agree almost entirely with our correspondent as to the evil and as to the propriety of finding a remedy for it. But we scarcely agree with him as to the causes of the evil and the remedies it requires. There is one class of persons who are grievously to blame for the crowded state of the out-patient department and for the irksome detention of patients in pain, and that is the out-patients themselves, or rather that large section of them who have no business to be out-patients at all. It is undeniable that thousands of them could get all the medical attention they need without detention at the house of a private practitioner, and for the payment of sums that are quite within their reach. This mode of procedure on their part would have the enormous advantage of bringing them and their families into medical contact with a practitioner of their neighbourhood, who would have some chance of becoming acquainted with their constitution and circumstances, and would acquire a human interest in their health and well-being. In the out-patient department they are mere units in a crowd. We need not say, too, that this large section of the frequenters of the out-patient department are not fit objects of charity. They are unfit, and the suspicion that they absorb the funds supplied by the charitable is a part of the explanation of the inadequate support of hospitals which we all lament. The clergy can do no greater service to the really fit cases for the out-patient department than by exerting their influence to deter others from using institutions which were never meant for them. But though we are of opinion that the number of cases of suffering from prolonged detention in the out-patient department mentioned by our correspondent would be much diminished by respectable people of the working classes and smaller tradespeople recognising that the out-patient room is no place for them, and being in fact rather ashamed to be seen there, we by no means entirely acquit the "governors and secretaries" of all blame for the abuses which everybody sees and by which it is calculated that one-fourth, or even one-third, of the metropolitan population comes into contact with the hospital system every year. The governors and secretaries are very much misrepresented if they do not connive at these abuses. Do they not parade these bloated numbers in their reports as facts to be proud of, as the basis for a still larger subscription list? Our sympathetic interest in hospitals is great and ever increasing. But this shall never prevent us from demanding that the out-patient department shall be reformed for various and important reasons, of which to-day we emphasise one—that those persons whose cases are grave and sad may have prompt attention from skilled officers, agreeing, as we do, with the Vicar of St. Philip's, Sydenham, that under present conditions such cases are often made grievously worse by prolonged attendance in the waiting-room.

WITH the death of Professor HUXLEY there passes away a man of robust mind and great intellectual power and intrepidity, an original and independent thinker, and a master of vigorous, masculine English, as well as a man of very wide range of thought, varied attainments, and rare learning. He was one of the most conspicuous figures of the latter half of this century in science, literature, philosophy, metaphysics, and education. Any contribution bearing his name was always read with avidity, because he wrote both vigorously and tersely, was singularly happy in his use of illustrations, with the additional charm of touches here and there of wit and humour and an occasional dash of poetry and pathos that afforded glimpses of the broad sympathies and pitifulness of his deeper nature. Apart from the scientific work he had accomplished, and the reputation he had won from the special jury of science, these qualities, and the generous, enlightened, and fearless character of his writings, made him a leader of popular thought and a reformer of popular misconceptions. As a strong swimmer, confident in his own powers, plunges into the stream and finds a pleasurable exercise in breasting the tide, so did HUXLEY love to sound the depths and encounter the difficulties of a controversial or abstruse subject. Some writers, like the late JOHN STUART MILL, have dwelt upon the mergence of individual character in a dead level of uniformity as the bane of modern civilisation: the manly independence and intellectual force and honesty of men like HUXLEY provide the best antidote. That he was regarded by some as too assertive and aggressively dogmatic in the expression of his views is of little importance now. Who cares to regard these things in recollecting the nobility of the man, his honesty and hatred of cant, his pride that preserved him from all mean and sordid motives, his manly sympathies with the sufferings of humanity, and his courage in following without wavering, or shadow of turning, what he conscientiously thought to be the light of truth and reason? Nature had endowed him with great gifts, and he bestowed them on his fellow-man with an open palm. On his sacrifices and laborious exertions in the cause of science, and on the bold and striking generalisations and the achievements he accomplished in that field, there is no need to dwell here, for these have been universally recognised by his friends and foes alike. As an educational lecturer he was admirable; his scientific knowledge and tone were as conspicuous as was his easy and lucid exposition, and, as we have said, his use of illustrations was always specially happy in that they really did illustrate what he was elucidating or describing. His writings are models in their way, so transparently clear that the reader can see to the bottom of the deepest subject, because their author had himself penetrated those depths and previously examined and ascertained the meaning underlying the phenomena he was describing. Not only had HUXLEY genius, but he had cultivated nature's rich soil with rare assiduity; he was an excellent classic, a modern linguist, a draughtsman, and a highly cultured man. And it may be confidently asserted that he exercised his powers with a dominating love of truth for its own sake, and an abiding sense of responsibility. As he has himself told us, he held the conviction that there was no alleviation for the sufferings of mankind except veracity of thought and action. It was this conviction that made him try to promote the increase of natural knowledge and encourage the application of scientific methods of investigation to all the problems of life. We

Digitized by Google

need scarcely dwell upon the fact that the medical profession may recall with pride that it had the great honour of numbering the late Professor HUXLEY among its members, and that he began his career and first made his mark whilst serving in the Royal Navy. But HUXLEY belonged to his generation and mankind. The news about a change of Government and a pending election, and the list of titular honours and distinctions conferred by the outgoing Government, which appeared in the papers contemporaneously with an obituary notice of the Right Honourable T. H. HUXLEY, will be obliterated from the memory like a last year's almanack, but his name will always remain on the scroll of fame of the Victorian age.

Annotations.

"Ne quid nimis."

THE METROPOLITAN PROVIDENT MEDICAL ASSOCIATION.

THE annual conference of gentlemen interested in this Association took place on the 21st ult. at the house of Mr. Claude Montefiore, 12, Portman-square, and included Mr. Gerald Balfour, M.P. (who presided), Lord Battersea, Sir Spencer Wells, Mr. T. Holmes, and others. It is impossible not to recognise the good motives of the gentlemen who constitute the executive of these dispensaries, and the amount of time and trouble they expend over the dispensaries. The provident principle has long been recognised by the medical profession. It is the essence of the club system which in an unostentatious way has been of immense service to the working-classes. It is difficult to say how a large section of these classes could be attended without some such adaptation to their means, though it is undeniable that not a few working-men have their own medical adviser for themselves and their families, and contrive to pay him two or three pounds a year, which the medical man appreciates as much as twenty or thirty from his richer patients. The sum is easily raised in a respectable family in these days when so many steady branches of employment are open to its various members. The Metropolitan Provident Medical Association has for its main object what every one must approve—the prevention of the abuse of hospitals. Its promoters are never weary in exposing this abuse and in trying to establish a system of friendly coöperation between hospitals and provident dispensaries, by which members of the latter institutions shall be favourably considered when their cases are grave enough to need the accommodation of a hospital. They have established twelve dispensaries in the metropolis, about half of which are self-supporting. The others need to be subsidised from the central fund, and receive help, like other dispensaries, from the Hospital Sunday Fund and the Hospital Saturday Fund. It cannot be said that this experiment has been a success. The medical men are poorly paid, the dispensaries without extraneous help would break down, and the hospitals are not materially relieved of work. In other words, the easy terms of the dispensaries and their general arrangements are not such as to attract the thousands who crowd the out-patient departments of our hospitals. The cause is not far to seek. At the hospitals medical work is given away, and the patients know that as a rule they will receive the advice of practitioners of the consultant class. Neither have these dispensaries succeeded in attracting the medical profession, whose members have regarded them with some suspicion. The reasons of this are not difficult to discover, and may be thus stated. The dispensaries compete with private practitioners; there seems no strict enforcement of wage limits; small handbills are printed which are apt to get into circulation, and that among the patients of other medical men; and those gentlemen who do join them are not rewarded by any adequate compensation for the work done. We should be glad to see some escape from these faults in institutions which have a provident basis. If the authorities of hospitals would do their duty and repress the crowds which throng their out-patient departments, the promoters of these dispensaries might be able to offer both the patients and the practitioners who attend them better terms. Meantime, it is enough to say that they are more in favour with laymen of a certain economic cast than with members of the medical profession. Like too many other medical institutions, they are worked at the expense of the medical profession and for the benefit of classes who can make a better recompense to their medical attendants than is provided for in the tariff of these dispensaries.

HOW DO PLANTS OBTAIN THEIR NITROGEN?

NOT the least remarkable part of the knowledge that we have gained during the last few years has been our insight into the life processes of plants, especially as regards their manner of assimilating nitrogen, admirably summed up by Professor H. Marshall Ward, F.R., in the current number of *Science Progress*. The mere narration of the details of the struggle with nature for the possession of this momentous secret is as exciting as the record of the discovery of the North-West Passage. After Sachs had determined the function of chlorophyll in splitting up the carbonic acid of the air into carbon and oxygen by means of the sun's radial energy, the question of the supply of nitrogen to plants came into prominence. As the leaves of the plant are bathed in an atmosphere of nitrogen, it was supposed first of all that the nitrogen was obtained from the air, but a crucial experiment of Lawes and Gilbert with different varieties of agricultural plants seemed to disprove this. The experiments, indeed, made it perfectly clear that a green plant was unable of its own accord to fix the nitrogen of the air. The only other sources of nitrogen are the nitrates derived from animal excretions, the decomposition of animal and vegetable tissues, and the nitric and nitrous acids produced by electrical discharges in the atmosphere. Nitrates are exceedingly soluble in water and are rapidly removed from the land by surface drainage, so that these sources seem hardly sufficient to account for all the nitrogen used by the vegetable world. In this dilemma a fresh path was opened to the investigators by the progress of bacteriology on the one hand, and of researches into the functions of the roots and root-hairs on the other. In a thimbleful of soil there are present from one to ten millions of minute organisms in more or less close contact with the rootlets of the plant. The mode of life of these bacteroids in relation to the plant was a fertile subject for investigation. There are present, of course, a certain number of merely destructive organisms, and a further cohort of nitrifying and de-nitrifying germs, but what of the others? Their function was not fully understood until 1887, when Professor Marshall Ward found that the soil contained a perfectly definite living organism that invades the tissues of leguminous plants, causing fleshy nodules to form on the rootlets. Further investigations by a number of observers since that time have elucidated the curious relations that exist between the plant and the bacteria of the soil. It appears that the organism, having entered the root hairs, stimulates the deep cells of the cortical tissues to form a layer

Digitized by Google

of hypertrophied cells. These cells are filled as fast as they are formed with quantities of bacteria, which do not injure the cells, but stimulate them to intense physiological action. During this time large quantities of carbohydrates are taken from the plant and converted into carbonic acid, the energy thus obtained being used to do the necessary chemical work in splitting up the nitrogen molecules obtained from the surrounding air and compelling them to enter into combination. When the activity ceases the partially disorganised contents of the nodule are absorbed by the plant, the shell, together with a few bacteroids that have escaped destruction, being rejected as débris. Leguminous plants seem to be the only ones capable of fixing nitrogen with the assistance of the bacteria of the soil, and a crop of peas or beans adds remarkably to the fertility of a field, so that by a proper succession of crops the farmer will be enabled to dispense to a large extent with nitrogenous manures. By the application of our growing scientific knowledge to practical agriculture there is no reason why our fields should not yield many times their present stores of food to supply the needs of our population and make it worth while again to grow English corn to feed English mouths.

THE GOVERNMENT OF THE WORKHOUSE.

THERE are few things of more importance to the development of our national character than an intelligent application of the Poor-laws. On the one hand, there is a tendency innate in all proper-minded persons to render the lives of their less fortunate brothers as little irksome as is possible under the circumstances; and, on the other, it is obviously expedient to control within moderate limits the practical expression of this spirit of pity and sympathy. In other words, in tempering justice with mercy it is necessary that the tempering process shall be guided by an intelligent estimate of the effects—immediate and remote—which such action is likely to produce. The condition of our workhouses throughout the country may, broadly speaking, be regarded as an index of the interest that is taken by the guardians in the several unions in the practical administration of the Poor-laws, and where we find bad management existing there we shall probably discover either a blameworthy ignorance on the part of the guardians of their duties and powers, or an equally culpable neglect of their responsibilities. The election of guardians held in December of last year was instrumental in introducing into power a large number of persons of varying degrees of education and intelligence, whose experience of Poor-law administration was practically *nil*, and whose knowledge of the duties and responsibilities of their office was in all probability but small. Although the education of these newly elected guardians in at least the recent history of the Poor-law is a matter of paramount importance, it will probably be admitted that some at least of those elected are hardly of the class to master all the complicated technicalities of the Poor-law as contained in the standard works on the subject, even although they are no doubt anxious to obtain a knowledge of their newly acquired duties. Under these circumstances we are glad to be able to welcome a little volume compiled by the editors of the *Poor-law Officers' Journal*, and published at 74, Market-street, Manchester, which contains so much of the General Consolidated Order of 1847 as relates to the workhouse, and also the subsequent Orders and Acts of Parliament dealing with workhouse management. There is, too, in the appendix of the volume the report of the recent Royal Commission on the Aged Poor, so far as it relates to in-door relief and the classification of the inmates; explanatory notes are added where necessary, and the whole forms a compact little volume which should, we think, be of the greatest service to all guardians. We are afraid that in the Poor-law, as also in public health administration by local bodies, there is sometimes too great a tendency to be guided exclusively by the clerk. In the volume to which we are here referring we would especially commend to the notice of guardians those parts having reference to visiting committees. We hear from time to time of scandals in our workhouses and infirmaries which are a disgrace, not so much to our Poor-law system, as some would infer, but to the guardians who fail to act up to the responsibilities which they have incurred. If the visiting committees, which, we are told, are usually appointed at the commencement of each financial year in accordance with the provisions of Article 148 of the General Consolidated Order, would do their duty and "carefully examine the workhouse once in every week at the least, examine the stores, and afford, so far as is practicable, to the inmates an opportunity of making complaints," and, in addition to this, from time to time make surprise visits, we venture to think that scandals, of which we too often hear, would diminish in number.

THE MILK-SUPPLY OF NEWCASTLE-UPON-TYNE.

DR. HENRY ARMSTRONG has recently presented to the Newcastle Sanitary Committee an interesting report upon this subject. Newcastle, we are told, consumes nearly 2,000,000 gallons of milk annually, part of which is produced by cows located in the city and its vicinity, and part imported by rail or steam-boat. Dr. Armstrong reports that, as a rule, the milk houses and milk vessels on dairy farms are kept "scrupulously clean and sweet," a condition of affairs which, we must confess, does not always obtain in southern England. Considerable progress has been made in Newcastle in the matter of cowhouses in recent years, and since July, 1892, when regulations under the Dairies, Cow-sheds, and Milk-shops Order were made, no less than thirty-nine cow-houses have been pulled down or closed. Under the regulations in question 800 cubic feet of space are prescribed for each cow, but there seems to be some difficulty in enforcing this amount, and we are told that this part of the regulations has not yet been put in force; in fact, from the 800 cubic feet standpoint 65 per cent. of the cowhouses are overcrowded, and Dr. Armstrong draws attention to the danger to the health of the cows of such overcrowding. There are in the borough no less than 488 places for the sale of milk by retail, but many of these are not, Dr. Armstrong states, suitable for the purposes of milk storage, and he draws attention to the difficulty of properly controlling persons who hawk about the streets milk taken from railway cans temporarily lodged in their premises, but who do not use these premises as sale shops. In that part of his report which deals with milk in relation to disease in cattle and in man Dr. Armstrong points out that different diseases of cows are transmissible by means of the milk to the persons who consume it, and that milk serves as a nidus for the development of the germs of the disease, both "before and after yield." In the matter of tuberculosis reference is naturally made to the recent report of the Royal Commission, and Dr. Armstrong remarks, we notice, that "the milk of cows with tuberculosis of the udder is much more virulent than that of animals affected with the disease in other parts only." It would seem, however, that in the opinion of the Commission, milk drawn from tuberculous cows whose udders were unaffected by the disease, was not at all potent for harm—for instance, in Paragraph 60 the Commissioners state: "According to our experience, then, the condition required for ensuring to the milk of tuberculous cows the ability to produce tuberculosis in the consumers of their milk is *tuberculous disease of the cow affecting the udder.*" (The italics are theirs.) The Newcastle Improvement Act of 1892 enacts that no dairyman shall sell the milk

Digitized by Google

of any cow which to his knowledge is affected with tuberculosis or milk fever, and the same Act also provides for the notification by dairymen of the same diseases. These are both excellent provisions, but it appears to us likely that their usefulness may be in some degree impaired by the presence of the words "to his knowledge," which would appear to offer a tempting loophole for escape from the provisions of the Act. With regard to the notification of tuberculosis and milk fever the provision has, it appears, been inoperative, and "no case has been notified." During the last four years an average annual number of 108 samples of milk have been analysed; but, as Dr. Armstrong remarks, this number is altogether inadequate to control a milk-supply of some 2,000,000 gallons, and arrangements have been made for increasing the number in future. In the conclusion of the report suggestions are submitted for the consideration of the committee, and among them we observe "that every cow with tuberculosis (proved or reasonably suspected) on a dairy farm should be slaughtered." No doubt slaughter is a very efficacious method; but perhaps in dealing with a cow only "reasonably suspected" such a proceeding would be a little too drastic, more especially when regard be had to the opinion of the Commission already quoted, and probably the isolation of the cow and the withdrawal of its milk from consumption would suffice. Dr. Armstrong's report should prove of much service to the sanitary committee.

THE DANGERS OF COCAINE.

FEW drugs in recent times have received more general commendation than cocaine; its advantages as a local anæsthetic, received with some incredulity when it was first introduced, have been so abundantly proved that there may be a tendency to overlook the fact that there are certain dangers attendant upon its too frequent or reckless employment. As a local anæsthetic it has won golden opinions where small operations were required upon superficial parts; in ophthalmic and laryngeal surgery it may fairly be said to have revolutionised the methods of a few years back. But every now and again warnings are brought forwards which indicate that with cocaine, as with opium and other modes of producing local or general anæsthesia, there is danger in the familiarity which breeds, if not contempt, at least disregard of ordinary precautions. Verdicts of misadventure are no consolation to those concerned, if there is an underlying conviction that the fatality might never have occurred if there had been any due appreciation of danger. Cocaine is a drug which shares with opium and many others the questionable credit of developing a "habit"—i.e., of leading, by the beneficent effects experienced after small doses, to a desire for the repetition of the relief; and as a consequence the dose employed tends to become greater, and the precautions which, perhaps, were taken at first are gradually relaxed. "Cocainism" is not so well recognised in this country as in America, but it undoubtedly exists as a form of self-indulgence or as a practice which, like morphinism, originally employed as a means of alleviating some chronic trouble, has ultimately developed into a form of self-indulgence, in which the need of restraint and of precautionary measures are entirely lost in the fascination of the relief afforded by the drug. In a recent inquest the evidence showed that the drug had been originally prescribed for the relief of pain in the gums, and the symptoms immediately preceding the termination were merely those of collapse; there was no indication of the amount employed or taken. In most cases collapse is the most marked feature, and this symptom may arise when the drug has been employed as a local application in the form of hypodermic injection or spray, and may frequently call for stimulant treatment after employment of the spray in laryngeal examinations. It must not be forgotten, however, that a true cocaine habit may be developed when the drug is taken internally in any quantity, and that this condition is occasionally marked by curious hallucinations and perversions of moral sense, which, if the use of the drug is not discontinued, may lead to more serious central disturbances. The summary of the whole matter may be expressed in the proverb that "fire is a good servant but a bad master." Cocaine, or any other drug which allays pain, has its limitations, and these are reached when the craving for the relief afforded leads to disregard of the attendant dangers.

ROYAL FREE HOSPITAL: THE OPENING OF THE NEW BUILDINGS.

WE print in another column a letter from Lord Dufferin announcing that the new front building of the Royal Free Hospital will be opened on July 22nd by the Prince and Princess of Wales. The charity thus honoured by Royalty has had a long and useful career, having been founded in 1828 and removed to its present site in Gray's-inn-road during the year 1842. It has no endowment, and, like most of the metropolitan hospitals, is under the necessity of making strenuous and persistent efforts to maintain an equilibrium between income and expenditure. Between 1855 and 1879 the north, south, and east wings were reconstructed, the old front building remaining until 1892, by which time it became so dilapidated that rebuilding was unavoidable. The cost of the new structure, together with a laundry, a modernised drainage system, fire-extinguishing appliances, and other necessary improvements, has been about £30,000, towards which sum the committee have obtained £24,000, thus leaving a balance of £6000 still to be raised. The hospital now contains 160 beds, and the wards are always filled with the most urgent and necessitous cases presenting themselves for admission, no letters of recommendation being required, only the poverty and sickness of the applicants being considered. The committee, therefore, in their need of £6000 make an urgent appeal for aid to the charitable public. In this application they are sustained by the confident assurance that the work which they are conducting under circumstances of so much difficulty, not only benefits the poor and afflicted, but promotes the cause of medical education by the thorough instruction which is here imparted to female students.

FURTHER CONTRIBUTIONS ON HELIUM.

NEW discoveries, however astonishing, soon get left behind by the advancing army of science, like milestones on the road of progress. Scarcely have we overtaken argon and helium when Professor W. Ramsay is promising us not one but two new elements belonging to the same series. According to his paper, read before the Chemical Society on June 20th, there is no doubt that argon and helium contain as a common ingredient a gas not hitherto identified, with a probable atomic weight of about 10 referred to hydrogen as unity; for two lines in the spectra of the newly discovered elements are absolutely identical. From the anomalous position of argon in the periodic scale, Professor Ramsay regards the presence of another element with argon, having an atomic weight of a little more than 80, as almost certain, and, indeed, this would account for many discrepancies. The velocity of sound in helium has been determined, and it has been proved that helium, like argon, is monatomic, and that all its energy is taken up in motion of translation, there being no internal work. It follows from this that the hypothetical element common to the crude helium and argon is also monatomic. The density of helium is about 2·2 as far as we can tell at present, and not 3·9 as wrongly reported previously. When the second

Digitized by Google

element has been separated from helium its density will be brought down still lower. To clear up a possible misconception we may state that argon has never been obtained from any other source than the air, and that helium has been extracted from various rare minerals by the action of acids. It is impossible for helium to exist in our atmosphere, as the gravitational force of the earth is not able to keep these light atoms, which are thrown off into space by the centrifugal force of the earth's rotation. All the uncombined helium of our planetary system is probably concentrated in the sun, unless that enormous planet Jupiter has managed to retain some. It is interesting to note that helium is by far the most insoluble gas known, for water dissolves only about half as much helium as hydrogen or nitrogen. This will afford a convenient means of separating helium from other gases, and as it seems to be contained in many rare minerals of the uranium and thorium type we may hope that before long larger quantities will be available for the purposes of experiment. Besides the isolation of the two hypothetical gases we have spoken of, Professor Ramsay looks forward to investigating the actual condition in which helium exists in minerals, for he has found that these substances will not reabsorb helium when once it has been extracted from them. The last meeting of the British Association was marked by the discovery of argon, and it is reasonable to hope that the forthcoming session may witness further additions to our knowledge of these remarkable gases.

MENTAL DISORDERS AND BODILY DISEASE.

A PAPER of great interest and suggestiveness by Dr. Goodall and Dr. Bullen on this subject appears in a recent number of the *Journal of Mental Science*, and the particular importance of this subject is at the present time much enhanced by the work recently carried out at the Royal Asylum, Morningside, by Dr. Bruce, with reference to the effect of thyroid treatment on the insane, to which we referred in a leading article in a recent number of THE LANCET.[1] This work was entered upon at a hint, so to speak, derived from the observation of the effect of intercurrent maladies upon mental states. It has long been recognised that in certain feverish conditions morbid mental states undergo a marked improvement, just as epileptic attacks so frequently cease during an acute illness, to recur during convalescence. The administration of thyroid gland substance, especially in doses which are to a certain degree toxic, is now known to be associated with a rise of temperature sometimes of several degrees, and it was thought by Dr. Bruce that by administering this potent substance to patients the subjects of chronic mental disorder, especially the forms in which subnormal temperature is the rule, some approach to the beneficial effect produced on the mental state by acute illness might be looked for. These expectations were not disappointed, and the degree to which they were realised will be found summarised in the leading article to which we have already referred. Dr. Clouston some years ago expressed the opinion that we shall some day be able to inoculate a septic poison and get a safe and manageable counter-irritant and fever by means of which acute attacks of insanity will be cured. This conception, which appeared only a few years ago to be both vague and visionary, may now be said to have entered into the field of practical mental therapeutics. The beneficial effects of an attack of erysipelas in cases of acute insanity and in certain cases of malignant disease are facts which are highly significant, and which seem to convey the suggestion that we have here the mutually destructive effects of one toxic process upon another, and Dr. Goodall and Dr. Bullen in this relation refer to several instances of mental disease in which there has been evidence of the presence of some toxic substance. Thus in a case of acute delirious mania Rasori described a bacillus in the subarachnoid fluid. Bianchi and Piccinino have reported a case of acute delirium in which a bacillus was found in the blood drawn during life, while other observers have made similar observations. Perhaps one of the most interesting points is that two observers have independently described a coccus in hæmatoma auris, and although its causal connexion with this phenomenon still remains to be proved its discovery seems to open up a way into a future full of promise. Much is to be hoped for from the concentration of attention on the acute mental cases, and from the association, in regard to these, of clinical and pathological observation as urged in the recent report of the Whittingham Asylum, Preston, by Dr. Wallis; and we cordially endorse the view expressed in the paper which is here immediately under our notice, that "for the elucidation of the problems connected with the influence of intercurrent maladies on mental disorders the association of the trained clinician and the laboratory worker, skilled in the methods of bacteriology and organic chemistry, is particularly needed."

[1] THE LANCET, March 9th, 1895.

MEDICAL WORK IN CHINA.

WE have received the report for 1894 of the Presbyterian Mission Hospital at Swatow. The most noticeable point about the report is the light it throws upon the curiously phlegmatic temperament of the Chinese, except as regards matters which concern their supply of food. Thus Dr. Cousland says that the rice harvest in the south failed, the importation of rice from the north was stopped, owing, we suppose, to the war, and in October it looked as if a rice riot were imminent. "Fortunately, the timely arrival of steamers relieved the acuteness of the situation. People were seen in the streets of Swatow actually jumping for joy at the sight of steamers coming into the harbour." Contrast this outburst of mental emotion with what follows. Speaking of the diminished attendance Dr. Cousland says: "Wild rumours as to the dreadful practices of foreign doctors in Hong-Kong on plague patients, *and perhaps the vague idea that China was fighting some other country*, have also had some effect on the attendance." Having read this, we cease to wonder at the following. There were 492 operations, 201 dental extractions, and a considerable amount of minor surgery not included in the foregoing numbers was performed, and yet "chloroform was administered only eighty-eight times, as the Hoklos have remarkably little sense of pain." This insensibility, both mental and bodily, probably accounts for the horrible severity of the Chinese criminal code and the agonising nature according to Western ideas of the punishment.

INSANITY AND COMMERCIAL DEPRESSION.

THE report for 1894 of the Inspector-General of the Insane for New South Wales affords some interesting details showing the connexion between an increase of insanity and a decrease of commercial prosperity. The years 1892, 1893, and 1894 were all years of commercial depression, and the increase in the numbers of insane persons on the official register was respectively 178, 113, and 162. The inspector-general points out that commercial depression operates in two ways in bringing under official care a number of insane persons in excess of the average. First it directly predisposes insanity, especially in the neurotic and weak-minded, who are unable to stand up against conditions of life more than usually hard; and secondly, by compelling persons formerly able and willing to support idiot and imbecile relatives to throw them on the charity of the State.

Digitized by Google

Be this as it may, if we turn to the table showing the occupations of those admitted, readmitted, and under care during 1894 we are struck by a rather curious fact. Adding together the numbers of those included in the professional and commercial classes the total comes to 344; whereas the numbers of those included under miners, labourers, seamen, and shepherds come to 1475. Of course, the percentage of these various classes to the total amount of the population ought to be taken into consideration, but it seems curious that sailors and shepherds should be included in the list. Perhaps loneliness may have somewhat to do with it in the case of the shepherd. A life in the wilderness is apt to engender mental trouble. "Vertebantur ad melancholiam" was said of the old hermits in the Egyptian desert; and there is a woeful story on record of a haggard man who crawled to an Indian station crying, "There is no God, but I have walked with the devil," and was recognised as one who had been sent to take charge of a lonely district by himself. "Man is a social animal," as Aristotle said, and perhaps the cares of town life, wearying as they are, are more than counterpoised by the daily communication between a man and his fellows.

THE POISON OF THE ORNITHORHYNCHUS.

WE have received a pamphlet from the Physiological Laboratory of the University of Sydney containing observations by Dr. C. J. Martin and Dr. F. C. Tidswell on the femoral gland of the Ornithorhynchus and its secretion, with an experimental inquiry concerning its supposed toxic action. It will be remembered that we noticed at some length in THE LANCET of March 16th the conclusions arrived at by Dr. Anderson Stuart on this subject. The essay before us contains a good historical *résumé* of our information in regard to the spur of the ornithorhynchus and the gland attached to it, from the first notice of it by Home in 1802, who thought the spur was a copulative organ, to Jamieson, who in 1817 discovered the gland connected with the spur, the duct of which traversed the spur, and the secretion of which he had observed to produce a poisonous effect on a man who had been endeavouring to capture a specimen after it had been wounded. Bennett and Owen were disinclined to admit that it was an organ of offence, whilst Dr. Anderson Stuart has no doubt that it is, and adduces cases of dogs which suffered severely from the action of the poison, and his opinion coincides with those of Dr. Martin and Dr. Tidswell. These observers have carefully examined the anatomy of the organ in question, with the following results. The glands are whitish, uniform, situated on each side of the spine over the acetabulum and the femur, and just outside the gluteus maximus, and rest on the rectus, iliacus, and glutei medius and minimus muscles. The duct emerges from the posterior half of the outer border of the gland, runs down the back of the leg to the tarsus, where it dilates into a sac and is then continued along the spur. The spur is about half an inch long and is attached to a supernumerary tarsal ossicle. The gland is invested by a layer of smooth muscle and is of a compound racemose type; the alveoli are buried by a single layer, or in one case by four layers, of epithelial cells, the contents of which are granular. The duct, though apparently single, contains two or three channels embedded in white fibrous tissue, without any admixture of smooth, muscular tissue. Neither in the living nor in the dead animal can the secretion be made to exude by pressure. Chemical examination of the secretion showed that it contains proteids, and that these consist chiefly of some form of albumin, with a little proteose, but no nucleo-albumin. The results of experiments on various animals showed that there was an analogy between the venom of Australian snakes and the poison of the platypus, since both owe their toxic properties to proteid constituents; that they both retard or prevent the coagulation of the blood when slowly introduced into the system in small doses; that they both cause intravascular clotting when injected into the veins in sufficient doses; that they both cause an almost instantaneous drop in the pressure of the blood; and that they both cause capillary hæmorrhages and œdema when locally applied. There is reason to believe that the secretion of the platypus is chiefly venomous at some particular season of the year, especially about the month of June.

SIR HENRY DUNCAN LITTLEJOHN.

GENERAL satisfaction will be caused throughout the profession, especially in Scotland, by the announcement that Dr. H. D. Littlejohn of Edinburgh is to receive the honour of knighthood. Dr. Littlejohn's ample claims to distinction are connected mainly with his labours in the cause of sanitation and public health, in the manifold departments of which he has long been a recognised authority. His medical career commenced more than fifty years ago, and he graduated as M.D. of Edinburgh University in 1847. To the general public he is chiefly known as the medical officer of health of Edinburgh. He has also filled the office of President of the Royal College of Surgeons of Edinburgh, and has for many years been Lecturer in Medical Jurisprudence at the Edinburgh School of Medicine.

CREDULITY AND FANATICISM.

THE remarkable ignorance and credulity of the lay mind with regard to any medical matter concerned with the process of generation is well shown by a case which occurred at Ballymacarrett, Belfast, and which is recorded in another column by one of our Irish correspondents. A young married woman gave birth to a child on May 4th, and went on satisfactorily for two days. She was then attacked with pain and vomiting, and a tumour was detected in the abdomen. A diagnosis of ovarian tumour was made and an operation advised. She was taken to the hospital, but no operation was permitted, and she died on May 11th. No post-mortem examination was allowed, and the common talk in the neighbourhood was that a second child existed and had not been delivered. Finally, the authorities determined to exhume the body and hold a post-mortem examination. On this being done on June 25th, a ruptured ovarian cyst with a twisted pedicle was found. The jury returned a verdict in accordance with the medical evidence and exonerated the medical men from blame. The case is only one more instance of what mischief and annoyance ignorant tongues can work.

CASTRATION FOR OVERGROWTH OF PROSTATE.

THE *New York Medical Record* of June 1st and June 8th reports the proceedings of the annual meeting of the American Surgical Association, the president being Dr. Fred. S. Dennis. *Inter alia*, an interesting discussion is given on the above subject. It was opened in a paper by Dr. J. William White of Philadelphia, Pa. Dr. White inclined to the view that the cause of prostatic enlargement was the survival of that function of the testicle which imparts masculinity to the individual and perpetuates the secretion of spermatic fluid long after it ceases to contain spermatozoa. He had collected 111 cases of double castration by competent surgeons for enlarged prostate in extreme and exaggerated forms which he said "had resulted in cures." All the same, he went on to show that twenty of these had died. In 87·2 per cent. rapid atrophy of the prostate follows, and in 52 per cent. great lessening of long-standing cystitis. In gauging the mortality, he thinks that twelve of the twenty fatal cases should in fairness be excluded, leaving 7 per cent. instead of 18 as the mortality. Even in the fatal cases

Digitized by Google

shrinking of the prostate had occurred before death. He thought the operation more promising than any alternative ones, as it is more easy of performance and free from the objection of subsequent fistula &c. From the discussion which followed it is clear that American surgeons are not yet quite satisfied with the evidence of the safety of the operation. Dr. L. S. Pilcher made a thoughtful speech, in which he said he thought the operation most indicated where the overgrowth was soft and glandular in nature. He detailed a case of operation in a man aged sixty-seven where gradual enlargement of the testicles had occurred. The operation was followed by delirium, pyrexia, albuminuria with casts, and death, in spite of primary healing of the wound. Dr. Pierson related three cases. In one, after good progress for six days, bad symptoms supervened. Opening up of the scrotal wound revealed gangrene, and death occurred on the eleventh day. Another speaker reported a case in which benefit followed the operation; but since the castration the patient had been subject to sudden flushings, heat, and sweating, which atropin and other remedies failed to relieve. Dr. Alexander feared that the operation was liable to be performed too readily from its being easy, and thought we had not yet passed the stage of physiological experimentation.

THE DAVOS INVALIDS' HOME.

A MEETING was held on June 27th at the house of Dr. Hermann Weber in support of this excellent institution, which has been the means of restoring to health and usefulness many whose limited resources could not otherwise have procured for them the advantages of the climatic treatment of Davos. The "Home" was founded eleven years ago, and has been entirely supported through the private benevolence of three English ladies, whose names are familiar to all those who have visited Davos. Mrs. Lord's unavoidable retirement through ill-health from the charitable work to which she has devoted so many years, and which owes everything to her admirable management, necessitates an appeal to public charity for the purchase of the freehold. With a view to collecting the necessary funds and to providing for the future management of the "Home," the following committee was appointed: the Right Rev. the Bishop of Marlborough, the Hon. Evelyn Ashley, Rev. D. Harford-Battersby, M.A., Rev. R. R. Resker, Dr. Hermann Weber, Dr. Symes Thompson, Dr. C. T. Williams, Dr. Wm. Ewart, and Mr. Arthur Herbert. None can better realise the importance of keeping the "Home" open for the benefit of the class to whom it has been so great a boon in the past than members of the profession. Their valuable help, whether direct or indirect, is earnestly invited. Contributions will be gratefully acknowledged by any members of the committee, or may be sent to Messrs. Williams Deacon, and Manchester and Salford Bank, Limited, 20, Birchin-lane, E.C., or 2, Cockspur-street, S.W.

THE PURIFICATION OF WATER.

THAT disease is conveyed by drinking-water is a truth which is now tolerably well established in the lay mind, but that water, even though not actually used for drinking or cooking, may convey enteric or other germs is far from being generally recognised. Professor Hankin, the bacteriologist to the Government of the North-West Provinces of India, has recently been studying the ways of native servants, with somewhat disquieting results. I have seen, he says, "a cook cooling a jelly by standing it in a small irrigation drain that ran in front of his cookhouse. The water running in this drain came from a well in which I had detected the cholera microbe. He cleaned a spoon by dipping it in the drain and rubbing it with his fingers; then he used it to stir the jelly." Professor Hankin's account of the way plates and dishes are washed during dinner is also calculated to make us speculate on what might happen, for the Oriental scullery boy seems to have a very fair notion, though of course in an amateur way, of cultivating microbes. In this country perhaps we are not so much exposed to danger from these causes; but anyone who has been in and out of the houses of the poor knows the painfully inadequate water-supply—the uncovered cisterns and the lack of cleanliness in the preparation of food which too often exist. We think that the issue of a small leaflet, now that August is coming on, pointing out the necessity for cleanliness in the preparation of food and the washing of plates and dishes, might be the means of obviating many a death from summer diarrhœa.

THE NEW MEDICAL OFFICER OF HEALTH FOR LAMBETH.

BY a majority of fifty votes Mr. Joseph Priestley, B.A. Lond., M.D. Edin., D.P.H. Cantab., was elected medical officer of health for the large parish of Lambeth by the vestry at their last meeting. Six candidates were selected to go before the vestry, and after being interviewed and questioned were balloted for by the eliminating ballot. Their names were: Mr. Alexander, medical officer of health, Poplar and Bromley; Dr. Bond, medical officer of health, St. Olaves and Holborn; Dr. Cooper-Pattin, medical officer of health, Norwich; Dr. Priestley, medical officer of health, Leicester; Dr. Wilde, medical officer of health, Bedfordshire County Council, and assistant medical officer of health, Croydon; and Dr. Wheaton, inspector under the Local Government Board, London. Dr. Joseph Priestley is well known in the public health service, more especially on account of the firm stand he made at Leicester during the small-pox epidemic, having to fight a very strong antivaccinating opposition. This opposition Dr. Priestley overcame successfully, without giving in one iota in regard to his views as to the efficacy of vaccination and revaccination in modifying and preventing attacks of small-pox, whilst his reports on the outbreak will go far to enhance that view. Before going to Leicester Dr. Priestley was assistant medical officer of health to the vestry of Camberwell, and whilst there had the advantage of being trained by Dr. Bristowe, F.R.S.

WE wish to call attention to the change that has been made in the date of the Prince of Wales's visit to Epsom. His Royal Highness, who will be accompanied by the Princess, will lay the foundation stone of the additional buildings to the Royal Medical Benevolent College on Monday next, July 8th (for full particulars see p. 37), instead of on Tuesday, July 9th, as originally arranged.

DR. RICHARD DEANE SWEETING, one of the medical inspectors of the Local Government Board, and late medical superintendent of the Western Fever Hospital, has won the Holt Scholarship at Gray's-inn. We congratulate our professional brother on his successful progress in the study of the law.

H.R.H. THE PRINCE OF WALES has graciously accepted the Chancellorship of the University of Wales in succession to the late Lord Aberdare.

BY direction of the Dean a special meeting of the School Committee will be held in Charing-cross Hospital to-day (Friday), at 3.30 P.M., to receive a suggestion from a member of the committee to found a "Huxley" memorial prize or scholarship.

DR. EDWARD WAYMOUTH REID, late Assistant Lecturer on Physiology at St. Mary's Hospital, Professor of Physiology in University College, Dundee, has been selected for one of the Grocers' Company's Research Scholarships.

Pharmacology and Therapeutics.

ESSENTIAL OILS.

THE relation of essential oils to the British Pharmacopœia and to trade purposes has lately been considered by Mr. J. C. Umney in the *Pharmaceutical Journal*. He thinks the use of the following so limited that they might be excluded from a new Pharmacopœia: chamomile, copaiba, rue, savin, and perhaps spearmint; but he recommends the inclusion of the following oils: bergamot, bitter orange, rose, and possibly synthetic winter-green oil (methyl-salicylate). He objects to the present restriction "distilled in Britain," thinking that it is only in exceptional cases that climate and soil influence for the better the character of the oil obtained from plants of the same species, and he maintains that it would be better for the pharmacopœial description, characters, and tests to include the source and the range of specific gravity at convenient temperatures. He also desires to see the following included: optical rotation, solubility in alcohol or other solvents, boiling point, and qualitative and quantitative chemical tests. The chief difficulty in the way of including the various essential oils in the Pharmacopœia lies in the fact that they are only to a relatively small extent employed in medicine, while enormous quantities are used for soap scenting, culinary and other industrial purposes by others than pharmacists. This has necessarily led to the importation of quantities of cheap and more or less impure oils. If these are required for trade purposes only, and not for employment by medical men, it is difficult to realise the need for their inclusion in the Pharmacopœia. Mr. Umney's paper contains a very careful summary of the characters of the principal essential oils handled by pharmacists, and it therefore calls for, and will doubtless receive, full consideration from those engaged upon the work of revision.

ARGENTAMIN AND ARGONIN.

As substitutes for ordinary aqueous solutions of nitrate of silver two organic compounds have been recently introduced which are said to have a still greater microbicidal action and to be less irritating than the nitrate. Argentamin consists of a solution of ten parts of phosphate of silver with an equal quantity of ethylene-diamine, $C_2H_4(NH_2)_2$, in a hundred parts water. This does not throw down chloride of silver when mixed with a solution of common salt, nor does it precipitate albumen. Clinically it is said by Dr. Schäffer of Breslau to act more energetically than a common nitrate of silver solution of the same strength, both destroying microbes of a pathogenic character better and also penetrating more deeply into the tissues. He found it especially valuable in the form of injections for gonorrhœa, and Lang has used it with good results in a large number of cases of abscesses of glands and of the connective tissue. Sometimes its irritant action is too great, but inconvenience from this may be avoided with due care. Another organic combination of silver has just been prepared by Dr. Röhmann and Dr. Liebrecht with casein. This new preparation, which they style argonin, contains only one quarter the amount of silver that the nitrate does. It is soluble in water, the solution being, however, opalescent and of a yellowish colour. It is said to be far less irritating to the tissues than argentamin. Like it, too, it forms no precipitate when common salt is added in solution, and according to Dr. R. Meyer of Breslau it has a remarkable microbicidal action, especially on the gonococcus.

GALLICINE IN OPHTHALMIC PRACTICE.

Gallicine, which is the methylic ether of gallic acid, is a white crystalline substance, soluble in hot water, in warm spirit, and in ether. Chemically it presents certain analogies with resorcin and with pyrogallol, and as these substances are of use in catarrhal and some cutaneous affections, it occurred to Dr. Mellinger, assistant to the Basle Professor of Ophthalmology, Dr. Schiess, to try the effect of gallicine in catarrhal conditions of the conjunctiva and in eczema of the eyelids and some other affections of the eye. The powdered substance, which is very light, is dusted into the eye or applied to the cutaneous surface by means of a brush, according to circumstances, in the same manner as calomel is employed. The application, which is made once or twice a day, is usually followed by a smarting sensation, which, however, soon passes off, but can be relieved by cold water compresses or entirely prevented by the previous use of cocaine. From an experience of some 200 cases Dr. Mellinger warmly recommends this remedy as superior in a good many eye affections to dermatol and gallinol. Conjunctivitis, whether catarrhal, suppurative, or phlyctenular, yielded to the gallicine treatment in a few days, and superficial keratitis, which had resisted the application of nitrate of silver, acetate of lead, compresses saturated with lead lotion, white precipitate ointment, atropin drops, &c., rapidly improved under gallicine. In phlyctenular affections gallicine has the advantage of being suitable, even when there is hyper-secretion, which, according to Dr. Mellinger, is a contraindication to the employment of calomel.

THE EXTERNAL APPLICATION OF PILOCARPINE IN NEPHRITIS.

Dr. Humbert Molliere has made some interesting researches on the value of pilocarpine applied externally in cases of nephritis. The treatment consists in rubbing into the skin an ointment composed of white vaseline (100 gr.) and nitrate of pilocarpine (5 to 10 centigrammes), and then covering up the part with cotton-wool and securing with bandages. The patient generally soon experiences a feeling of comfort, dyspnœa abates, and respiration becomes more regular, and only in very rare cases is the treatment badly borne. Perspiration quickly occurs, and is very profuse, in spite of the small quantity of alkaloid used, and at the same time there is abundant diuresis, and Dr. Molliere has drawn up interesting charts, showing a rise and fall in the quantity of urine corresponding to the pilocarpine applications. All varieties of nephritis have been treated by this method, but the best results have been obtained in acute cases, where the albumen has often quickly disappeared and a general amelioration of symptoms rapidly taken place, these good results being chiefly attributed to diminished congestion caused by the drug. Less favourable cases are naturally those in which the cardio-vascular system has already become secondarily affected. Where actual uræmia has set in this method is not so satisfactory, but is found to be successful if applied after the more pressing symptoms have been relieved by more energetic methods. The physiological action of pilocarpine when thus applied is found to be almost entirely local, and does not cause excessive secretion of the salivary and other glands, as it does when given by the hypodermic method.

We noticed in this column recently a preparation called airol, mentioning that it had been used with success as an antiseptic and styptic dressing. We are asked to say that the sole agents for this substance are Messrs. R. W. Greeff and Co., of 3, Eastcheap, E.C., to whom inquiries should be directed.

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF HEALTH FOR THE ADMINISTRATIVE COUNTY OF LONDON.

III.[1]

THE only other topic in Mr. Shirley Murphy's report to which space permits allusion is a special report to his authority on the water-supply of London. On the issue of the report of the Royal Commission on Metropolitan Water-supply the County Council referred it to their medical adviser for his opinion; and this, when received, was held to be of so great public interest as to render expedient the printing of it for general circulation. It accordingly appears as an appendix to the annual report before us. The general drift of the conclusions arrived at by the Commission as to the wholesomeness of the London drinking water is matter of common information; it is far otherwise, however, with regard to the evidence upon which these conclusions are supposed to have been based, and this evidence has therefore been subjected to detailed and searching criticism in the appendix referred to. Mr. Shirley Murphy passes in review much of the

1 Parts I. and II. were published in THE LANCET of June 22nd and 29th respectively.

Digitized by Google

expert evidence produced, his remarks upon this, and the judgment of the Royal Commission thereupon, being given by Mr. Shirley Murphy under the following headings: (1) Dilution of polluting matter in water; (2) viability of the typhoid bacillus; (3) number of organisms in water required to produce disease; (4) storage and filtration of water; (5) evidence of experience as to typhoid fever prevalence (especially that dealt with by Dr. Barry in his report on the typhoid fever epidemic in the Tees Valley; and (6) definition of the term "efficient filtration" of drinking-water. Mr. Shirley Murphy's remarks and arguments under each of the above headings are clear, forcible, and apposite, and, whether they meet with general acceptation in our profession or not, they certainly leave us in no doubt of their author's determination to secure in future and to maintain the utmost possible purity in the water-supply of the metropolis. In many important points Mr. Shirley Murphy traverses the report of the Royal Commission and gives his reasons for so doing, which are in all cases weighty and evince a thorough acquaintance on his part with the minutest details of the subject.

It is very obvious that the reason why the medical officer of the County Council regards the question of water-supply as of primary importance from a public health point of view is because of the admitted tendency of certain fatal diseases, especially typhoid fever and cholera, to disseminate themselves through the agency of drinking water. We strongly suspect, therefore, that the question of our water-supply is to Mr. Shirley Murphy very much on all fours with the question of typhoid fever (and possibly cholera) prevalence in the metropolis. In this attitude towards the water question he may rely upon the hearty support of the medical profession. It is probably immaterial to Mr. Shirley Murphy whether the water undertakings of the metropolis continue, as at present, in the hands of a number of private companies, or whether these rights are acquired on behalf of the public by the London County Council, as recent events would seem to render it probable that they will be at no very distant period from the present. But he would have our complete sympathy did he contend, as he is obviously entitled to do, that the officer upon whom devolves the chief guardianship of the public health of this vast metropolis should enjoy every facility for satisfying himself that those who provide the public with drinking-water adopt every known device for protecting that commodity from contamination. This is not a matter of mere sentiment. It is true that, according to the table published in another part of Mr. Shirley Murphy's report, typhoid fever mortality has shown a continued decrease during the last two complete decennia, and, in fact, down to the end of 1892; but the fact is a disquieting one that in the year 1893 a very serious rise in the mortality from this disease was observed. There does not appear to have been any noteworthy change in the sanitary condition of London which could account for this increase, and although the report contains no indication of the kind it is at least conceivable that in searching for its cause the medical officer may have desired to examine carefully the relation of water-supply to the local and general prevalence of the disease. Under existing arrangements it is very evident that any effective supervision of the metropolitan water-supply as a whole by the medical officer of the County Council is impracticable, and this for reasons which on reflection will be sufficiently apparent.

Returning now to the report of the Royal Commission, we find that the Commissioners insist very strongly on the necessity of proper treatment of the river water as a condition of its admissibility for drinking purposes. They state explicitly that the water which flows down to the intakes must be carefully subjected to certain processes of subsidence and filtration before it is brought into a suitable condition for delivery and consumption, and that the quality of the water when delivered depends largely on the thoroughness with which these processes are carried out. They do not go the length of prescribing exact regulations as regards the process of filtration, subsidence, &c., but they conclude their report with the following incisive statement: "We cannot shut our eyes to the fact that the provision for these processes [filtration &c.] differs enormously in the different companies, and in some of them is, to our mind, inadequate. Regulations on these matters should be drawn up after competent inquiry, and adherence to these regulations should be strictly enforced." Of this important judgment Mr. Shirley Murphy pertinently remarks that "the necessary corollary to the report of the Royal Commission on Metropolitan Water-supply is the issue of another Royal Commission to make such inquiry and such experimental investigation as may be required to determine the precise conditions to which polluted streams must be subjected in order to make their water uninterruptedly fit for domestic use." Mr. Shirley Murphy closes his most valuable and interesting report with these weighty sentences, which we give *verbatim*. "In view of the changes effected in the rivers, and subsequently in the filters, the risk to Londoners is, I believe, small, and certainly intermittent, and, indeed, may be thought of as comparable to those possibilities of injury from accident in the street to which every human being is subject during the whole of his life. The risk, indeed, is to each a possibility and not a probability, *but, such as it is, I believe it exists.* If we recognise, as I believe we may, that the safety of London residents is dependent upon the efficiency with which deleterious matter in the London rivers is by artificial means removed from the water supplied to the metropolis, the conditions under which this removal is to be continuously ensured must obviously be determined with absolute precision, and *an administration must be provided to secure that the object in view shall be attained.*" This is the deliberate conclusion arrived at by the medical officer of health of the administrative county of London, writing under a keen sense of responsibility, and as such we trust it will be appreciated as it deserves and acted upon by the administrative authority to whom this report is addressed.

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

THE School Board is developing a large amount of casuistry. In our issue of June 8th we called attention to the following resolution passed by the Board on the motion of Mr. Sharp:—"That the West Lambeth Divisional Committee be authorised to appoint for one year, upon the under-mentioned conditions, six doctors in that division to examine cases in which the medical certificate produced is considered by the divisional superintendent to be doubtful, or in which it is desirable to have a definite medical opinion. (*a*) That each case be first referred to the divisional member in charge of the school where the child ought to attend. (*b*) That a payment of 2*s.* 6*d.* shall be made for each case examined. (*c*) That the number of cases to be dealt with in this manner shall not exceed 100 in a year. (*d*) That the names of the doctors selected shall be forwarded to the magistrates having jurisdiction in the division." Mr. Athelstan Riley (whose amendment that all words after "produced" in the first paragraph should be struck out and "not signed by a properly qualified medical man" substituted was rejected) asked Mr. Sharp at the meeting of the Board on June 27th the following questions, amongst others:—

1. The names of the doctors in the Tower Hamlets and East Lambeth divisions who have consented to examine medical certificates considered by the divisional superintendents to be doubtful.
2. The number of certificates signed by properly qualified medical men in the above divisions which, being considered by the divisional superintendents to be doubtful, have been submitted for examination to the aforesaid doctors.

Digitized by Google

3. The proportion these bear to the total number of certificates issued in these divisions.

4. Whether the certificates signed by the aforesaid doctors are examined with (*a*) the knowledge and (*b*) the permission of the signatory in each case.

The following is the answer by Mr. Sharp (Chairman of the School Accommodation and Attendance Committee) to the foregoing questions:—

"It may be well to premise my remarks by observing that Mr. Riley labours under a misconception in assuming that the local medical men appointed by the Board have consented to 'examine medical certificates,' or that medical certificates will be 'submitted for examination to the aforesaid doctors.' These local medical men have been appointed 'to examine cases in which the medical certificate produced is considered by the divisional superintendent to be doubtful, or in which it is desirable to have a definite medical opinion.'"

Mr. Sharp then said that categorical answers would be misleading to the Board, so he preferred to make the following statement. After quoting his letter, which appeared in our columns of April 30th, 1895, he continued:—

"From the foregoing statement it will be seen that it is incorrect to suppose that all the cases which have been submitted to the local medical men appointed by the Board have been cases in which certificates have been given by other medical men, but which have been considered for some reason or other to be unsatisfactory. As a matter of fact, so far as I have information, the majority of the cases which have been submitted to these gentlemen have been cases in which no medical certificate has been produced by the parent, and in which it was considered by the divisional members to be difficult, if not impossible, to obtain such certificate. With reference to the latter cases, I might mention that, in some parts of London, at any rate, I have evidence that district medical officers of the guardians refuse to furnish, without payment, such certificates to persons in receipt of parochial medical relief. In these cases, therefore, the divisional committee must, in order to satisfy themselves as to the correctness, or otherwise, of the statement made by the parent as to the alleged illness of the child, either at once proceed with the prosecution before a magistrate or obtain a medical opinion in their own behalf. In those cases in which the child is ascertained to be unable to attend school, the Board are saved both the expense and the odium of unsuccessful legal proceedings, and the parent is saved the unnecessary pain and annoyance of a prosecution before a magistrate."

We should like to know what is the difference between "examining medical certificates considered to be doubtful" and "examining cases in which the medical certificate is considered to be doubtful." After this preface Mr. Sharp changed his ground and went on to explain that most of the cases submitted to the medical men were those in which no medical certificate had been obtained. If this is all the Board wanted why did it not accept Mr. Riley's amendment of May 30th?

Mr. Sharp's statement is simply playing with words. We will put the whole case in plain language. 1. The Board, by means of its divisional superintendents, considers certain medical certificates to be doubtful. 2. These certificates are presumably signed by qualified medical men. 3. The Board has appointed certain other medical men to examine these particular cases in which the certificate is considered doubtful. 4. That is to say, the Board has appointed one set of medical men to revise or examine, or set aside the diagnosis and opinion of another set of medical men. Let Mr. Sharp deny this if he can without beating about the bush. We warn the School Board, as we warned it in our issue of June 8th, that the result will be that no medical man will sign certificates at all, but will rather give evidence in case of a prosecution, and then, as Mr. Sharp pathetically puts it, the Board will "incur the odium of unsuccessful legal proceedings," and, in our opinion, it will well deserve this result.

CONSECRATION OF THE RAHERE LODGE OF FREEMASONS.

SATURDAY last was a red-letter day for St. Bartholomew's Hospital. In the great hall of the hospital a new Masonic Lodge was consecrated, named after Rahere, the founder of the hospital seven and a half centuries ago. Everything combined to make the function a success—a bright and sunny summer's afternoon, the presence of H.R.H. the Prince of Wales, the Grand Master, and a brilliant representative gathering of those whose names are equally well known in Masonry and Medicine.

At 5 o'clock lodge was opened, the Master's chair being occupied by Bro. E. Letchworth, Grand Secretary. Shortly afterwards the Prince of Wales arrived, accompanied by the Crown Prince of Denmark, who is Grand Master of the Freemasons of his own country. The Earl of Lathom, Pro-Grand Master of England, acted as consecrating officer and then took the chair. He was supported on his right by the Prince of Wales and the Crown Prince of Denmark, while the Senior Warden's chair was occupied by Lord Roberts of Candahar, Grand Senior Warden, the Junior Warden's chair being filled by Lord Skelmersdale. The duties of director of ceremonies were undertaken by Bro. Frank Richardson; the Dean of Gloucester, Grand Chaplain, acted as chaplain; and Bro. P. H. Waterlow, Past Grand Deacon, as inner guard.

The brethren received the two Grand Masters in due Masonic fashion, and accorded to each the salute due to his rank. The lodge presented a very brilliant spectacle, over 300 grand officers and brethren being present. Among them we noticed:—Viscount Dungarvan, Provincial Grand Master of Somerset; Colonel Le Gendre Starkie, Provincial Grand Master of East Lancashire; General Laurie, Past Grand Warden; W. M. Stiles, Grand Treasurer; Rev. Cooper Smith, D.D., Past Grand Chaplain; Lennox Browne, Past Grand Director of Ceremonies; R. Loveland Loveland, President of the Board of General Purposes; R. Horton Smith, Q.C.; H. F. Frost, Grand Organist; E. Cutler, Q.C., Past Grand Organist; Dr. Balfour Cockburn, Provincial Grand Master of Guernsey and Alderney; Dr. Hugh Mackintosh and Bro. Chas. Martin, Past Assistant Grand Directors of Ceremonies; the Earl of Euston, Provincial Grand Master, Northamptonshire and Huntingdonshire; Alderman Walter Vaughan Morgan; General J. C. Smith, Past Grand Master of Illinois. There were present a large number of medical brethren, including Bros. Reginald Harrison, Henry Morris, Edmund Owen, W. P. Herringham, Samuel West, Arbuthnot Lane, A. A. Bowlby, R. J. Reece, Essex Wynter, Leopold Hudson, Howard Tooth, Alban Doran, W. H. H. Jessop, Bruce Clarke, H. J. Waring, C. A. Parker, Danford Thomas, and F. W. Clark.

The impressive ceremony of the consecration was proceeded with, the Earl of Lathom giving the invocation, while the Dean of Gloucester delivered the oration, and the anthems were sung by Bros. Frost, Kenningham, Fryer, and Stubbs. The Grand Master then constituted the lodge, the following officers being appointed:—Bros. Clement Godson, M.D., P.G.D. (W.M.); Thomas Trollope, M.D., P.G.D. (Acting I.P.M.); Alfred Cooper, F.R.C.S., P.G.D. (S.W.); W. J. Walsham, F.R.C.S., P.M. (J.W.); D'Arcy Power, F.R.C.S., P.M., P.G.J.W. Warwickshire (Treas.); T. G. A. Burns, M.R.C.S., P.M., P.P.G.D. Surrey (Sec.); Walter Gripper, M.B., P.M. (S.D.); Phineas S. Abraham, M.D. (J.D.); G. H. R. Holden, M.D. (I.G.); F. Swinford Edwards, F.R.C.S., P.M. (D.C.); J. H. Gilbertson, M.R.C.S., P.M., P.P.S.G.D. Herts (Stwd.); C. B. Lockwood, F.R.C.S., W.M. 1150 (Stwd.); C. P. White, M.B. (Stwd.); Ernest Clarke, F.R.C.S. (Org.); Madden, Librarian of St. Bartholomew's Hospital (Tyler).

Among the other founders of the Lodge are Bros. W. Haig Brodie, B. Latter Tandy, A. G. R. Foulerton, H. D. Lanchlan, G. H. Forman, J. E. Sandilands, C. A. Parker, A. A. Bowlby, F. W. Clark, W. T. Partridge, J. Pickett, and R. J. Reece.

The first act of the new Lodge was to enrol its first honorary member in the person of the Prince of Wales. The Benediction having been pronounced, Their Royal Highnesses took their departure, and on leaving the hospital received an ovation from the students gathered in the quadrangle. The guard of honour was furnished by the St. Bartholomew's Hospital Company of the Volunteer Medical Staff Corps. The brethren afterwards adjourned to a banquet at the Albion, Aldersgate-street, the toast of "The Visitors" being responded to by General Smith of Illinois.

We wish this new professional lodge every success; it has received a magnificent christening, and the number of joining members is already very large.

A MAHOMEDAN DOCTOR ON THE MECCA PILGRIMAGE.

MUCH has been written concerning the pilgrimage to Mecca, but, as a rule, such writings are somewhat one-sided. Either the writers are Mahomedans who know nothing of the Western exigencies with regard to sanitation, or else they are not Mahomedans, and are therefore out of sympathy with the pilgrims, are not allowed to approach the

Digitized by Google

holy places, and consequently often criticise what they have not been able to see. Dr. Saleh Soubhy, as Doctor and Laureate of the Paris Faculty of Medicine, may be expected to take a Western European view of the sanitary difficulties attending the pilgrimage; while, as a good Mahomedan, he is in full sympathy with the pilgrims. This sympathy does not render Dr. Soubhy blind to the grave dangers caused by the utter want of sanitation. Speaking of the town of Djeddah, where the pilgrims land, he says: "The cleansing of the town is a matter of the utmost simplicity; the rain does this work, and I must hasten to add that it only rains once or twice in the year—and then! It is not necessary to make a great effort of imagination to have some idea of the state of affairs within the town. The entire surface of the soil is encumbered with the débris of vegetables, with spoilt fruits, and refuse of all descriptions, and giving off all sorts of odours. Horned animals, donkeys, horses, camels, and wild dogs leave the trace of their passage, but we must not complain of this, for the dogs and goats which wander everywhere are, after all, the only scavengers of the town, as they eat much of what would otherwise decompose on the soil. On the other hand, the population which crowd on a relatively restricted space have a system of drainage that is really surprising. It is a country of expedients. Nothing is more simple. When a cesspool is full a hole is dug close at hand and the contents of the cesspool are emptied into it. The hole is then covered over. Of course, infiltrations from these holes reach the neighbouring wells, whence the water is drawn which the pilgrims drink." When we consider the great heat that prevails in the daytime, and the damp that reigns at night, it is not surprising that cholera often breaks out at Djeddah. The water is extremely foul. Large animalcula can be seen in it, even without the aid of a microscope. The Turkish Government has given a considerable sum to construct an aqueduct to bring good water to the town, but somehow the canal has never worked properly. This failure is attributed to the action of the proprietors of the wells, who desire to preserve their lucrative privilege of selling foul water to the camel drivers and pilgrims.

Dr. Soubhy next protests against the folly of women attempting the pilgrimage during the period of gestation. He describes how the oscillatory movement of the camel produces miscarriages, followed frequently by hæmorrhage and the death of both mother and infant. The caravan, however, cannot stop, and it is impossible to nurse efficiently the mothers while the march continues. If any portion of the caravan stopped it would certainly be attacked by the Bedouins, who, Dr. Soubhy explains, are not true Mahomedans. On questioning a Bedouin as to the nature of his harvest he cynically replied, "My harvest is the pilgrim." Speaking of Mecca, Dr. Soubhy contents himself with saying that the condition of the town is very similar to what he saw at Djeddah. Nor does he say anything about the danger of contamination at the holy well of Zimzim. He simply relates that, according to popular belief, this well leads to Paradise. Consequently several pilgrims have thrown themselves into the well. As the bodies were never recovered it is natural to conclude that there are subsoil currents of water of considerable dimensions and power. This may be some protection. The Sultan has, however, now caused a high railing to be placed round the well so that the faithful cannot so easily jump into the water, and must perforce wait till a more natural death opens the gates of Paradise. Speaking of the Courban-Baïran festival, Dr. Soubhy estimates that at Mouna some 900,000 animals are sacrificed. This custom, at least, he has the courage to denounce. "It is easy to imagine what dangers this state of things may engender, what epidemics may be caused by these thousands of carcases in putrefaction, and how insufficient is the recent order, emanating from the Turkish Government, to bury this multitude of carcases." To burn the carcases and convert them into animal manure would be a better and more profitable solution of the problem.

In an appendix dealing purely with the sanitary question Dr. Soubhy suggests that a railway from Djeddah to Mecca, then to Medina and Yambo, would pay and would save a great loss of life resulting from the painful journeys on foot across the deserts. He also urges that children under ten years of age, women in the period of gestation, the old and infirm, those who have not been vaccinated within three years, and those who have not sufficient means for their maintenance, should not be allowed to embark on the pilgrimage; that those who are allowed to start should have a circular given them indicating what sort of clothes and provisions they should take; and that portable pharmacies should form part of the luggage of every caravan. There are no pharmacies, it appears, at Mecca, Mouna, and Yambo, yet thousands of pilgrims pass through these places suffering from diarrhœa, fever, purulent ophthalmia, and abscesses. Then the Red Sea ships are not only overcrowded by pilgrims, but also by the unnecessary luggage they take with them; and we are assured that there are often more pilgrims on board than the number sanctioned by the law. Nor are the rules as to the presence on board of a surgeon and of a medicine chest strictly observed. As for the sanitation of the towns, as there is the desert close at hand it would be easy enough to dispose of the sewage if a system of drainage was established.

Finally, Dr. Soubhy quotes the Prophet, who said, "You must avoid entering a country contaminated by an epidemic, so as to respect the will of God (God having said, Thou shalt not throw thyself into danger), and you must not leave a contaminated country, so as not to show that you are flying from the will of God." In accordance with this Dr. Soubhy proposes that pilgrims from the south—India, Java, &c.—coming from countries where cholera is endemic should visit Mecca alternate years, taking the uneven numbers, 1895, 1897, &c. Pilgrims from the north—Turkey, Egypt, Morocco, Algeria, &c.—could go in the years with even numbers, 1896, 1898, &c., and thus avoid meeting those who came from cholera-infected countries, and in this manner carry out the precept laid down by Mahomed.

THE NEW WATER SCHEME FOR BELFAST.

ON June 25th, on the invitation of the Chairman of the Belfast Water Commissioners, a number of Belfast merchants and others visited the "Silent Valley," the site of the proposed new reservoir, which it is thought will be completed within another year. This Silent Valley is situated in a remote but charming district in the Mourne Mountains, about five or six miles from the well-known seaside resort, Newcastle, in county Down. This new water scheme is by far the most important ever undertaken for Belfast, and it is said it will cost upwards of three-quarters of a million pounds sterling. The new catchment area is upwards of 9000 acres in extent, but it can be added to in the future. It has an elevation varying from 450 ft. to nearly 2800 ft. above sea-level, and it consists of high mountain slopes, largely composed of granite and boulders on the surface; hence it is of the very best description for a domestic water-supply. Another advantage it possesses is that it is free from cultivation and pollution of any kind, is uninhabited, and is in close proximity to the sea. The whole of the lands in this area will be purchased by the Belfast Water Trust to preserve its present character and to prevent risk of any future pollution. At present the water is collected by the Kilkeel and Annalong rivers, which empty themselves into the sea between Kilkeel and Newcastle. The Kilkeel river will be intercepted in the "Silent Valley" by means of a large storage reservoir having an earthen embankment some 520 yards long across the valley, and it will be upwards of 90 ft. high over the present river-bed. The top water area will be nearly 250 acres, and the total holding capacity will be 2850 million gallons of water. The total supply available from the whole of the Mourne districts will be, when fully developed, about 30,000,000 gallons per day. The supply will be drawn from this reservoir for use in Belfast through a number of large-geared valves at different levels on the outlet standpipe, which will allow the water to pass in large or small quantities through the main outlet tunnel into the main gravitating conduit, which will be formed of concrete, having a maximum carrying capacity of 30,000,000 gallons per day, the size being 5 ft. 6 in. by 5 ft. 6 in., and with a regular fall of 18 in. per mile. The main conduit will be continued along the mountain slopes to near Newcastle, where it will be carried through Slieve Donard and St. Thomas's Mountains in a tunnel some two and a quarter miles in length, with a fall of 12 in. per mile, and a maximum capacity of 30 000,000 gallons per day. Some parts of this tunnel will be 600 ft. below the surface of the ground. The service reservoir will be made large enough to meet the demands of the city, having a storage capacity

3. The proportion these bear to the total number of certificates issued in these divisions.

4. Whether the certificates signed by the aforesaid doctors are examined with (*a*) the knowledge and (*b*) the permission of the signatory in each case.

The following is the answer by Mr. Sharp (Chairman of the School Accommodation and Attendance Committee) to the foregoing questions:—

"It may be well to premise my remarks by observing that Mr. Riley labours under a misconception in assuming that the local medical men appointed by the Board have consented to 'examine medical certificates,' or that medical certificates will be 'submitted for examination to the aforesaid doctors.' These local medical men have been appointed to examine cases in which the medical certificate produced is considered by the divisional superintendent to be doubtful, or in which it is desirable to have a definite medical opinion.'"

Mr. Sharp then said that categorical answers would be misleading to the Board, so he preferred to make the following statement. After quoting his letter, which appeared in our columns of April 30th, 1895, he continued:—

"From the foregoing statement it will be seen that it is incorrect to suppose that all the cases which have been submitted to the local medical men appointed by the Board have been cases in which certificates have been given by other medical men, but which have been considered for some reason or other to be unsatisfactory. As a matter of fact, so far as I have information, the majority of the cases which have been submitted to these gentlemen have been cases in which no medical certificate has been produced by the parent, and in which it was considered by the divisional members to be difficult, if not impossible, to obtain such certificate. With reference to the latter cases, I might mention that, in some parts of London, at any rate, I have evidence that district medical officers of the guardians refuse to furnish, without payment, such certificates to persons in receipt of parochial medical relief. In these cases, therefore, the divisional committee must, in order to satisfy themselves as to the correctness, or otherwise, of the statement made by the parent as to the alleged illness of the child, either at once proceed with the prosecution before a magistrate or obtain a medical opinion in their own behalf. In those cases in which the child is ascertained to be unable to attend school, the Board are saved both the expense and the odium of unsuccessful legal proceedings, and the parent is saved the unnecessary pain and annoyance of a prosecution before a magistrate."

We should like to know what is the difference between "examining medical certificates considered to be doubtful" and "examining cases in which the medical certificate is considered to be doubtful." After this preface Mr. Sharp changed his ground and went on to explain that most of the cases submitted to the medical men were those in which no medical certificate had been obtained. If this is all the Board wanted why did it not accept Mr. Riley's amendment of May 30th?

Mr. Sharp's statement is simply playing with words. We will put the whole case in plain language. 1. The Board, by means of its divisional superintendents, considers certain medical certificates to be doubtful. 2. These certificates are presumably signed by qualified medical men. 3. The Board has appointed certain other medical men to examine these particular cases in which the certificate is considered doubtful. 4. That is to say, the Board has appointed one set of medical men to revise or examine, or set aside the diagnosis and opinion of another set of medical men. Let Mr. Sharp deny this if he can without beating about the bush. We warn the School Board, as we warned it in our issue of June 8th, that the result will be that no medical man will sign certificates at all, but will rather give evidence in case of a prosecution, and then, as Mr. Sharp pathetically puts it, the Board will "incur the odium of unsuccessful legal proceedings," and, in our opinion, it will well deserve this result.

CONSECRATION OF THE RAHERE LODGE OF FREEMASONS.

SATURDAY last was a red-letter day for St. Bartholomew's Hospital. In the great hall of the hospital a new Masonic Lodge was consecrated, named after Rahere, the founder of the hospital seven and a half centuries ago. Everything combined to make the function a success—a bright and sunny summer's afternoon, the presence of H.R.H. the Prince of Wales, the Grand Master, and a brilliant representative gathering of those whose names are equally well known in Masonry and Medicine.

At 5 o'clock lodge was opened, the Master's chair being occupied by Bro. E. Letchworth, Grand Secretary. Shortly afterwards the Prince of Wales arrived, accompanied by the Crown Prince of Denmark, who is Grand Master of the Freemasons of his own country. The Earl of Lathom, Pro-Grand Master of England, acted as consecrating officer and then took the chair. He was supported on his right by the Prince of Wales and the Crown Prince of Denmark, while the Senior Warden's chair was occupied by Lord Roberts of Candahar, Grand Senior Warden, the Junior Warden's chair being filled by Lord Skelmersdale. The duties of director of ceremonies were undertaken by Bro. Frank Richardson; the Dean of Gloucester, Grand Chaplain, acted as chaplain; and Bro. P. H. Waterlow, Past Grand Deacon, as inner guard.

The brethren received the two Grand Masters in due Masonic fashion, and accorded to each the salute due to his rank. The lodge presented a very brilliant spectacle, over 300 grand officers and brethren being present. Among them we noticed:—Viscount Dungarvan, Provincial Grand Master of Somerset; Colonel Le Gendre Starkie, Provincial Grand Master of East Lancashire; General Laurie, Past Grand Warden; W. M. Stiles, Grand Treasurer; Rev. Cooper Smith, D.D., Past Grand Chaplain; Lennox Browne, Past Grand Director of Ceremonies; R. Loveland Loveland, President of the Board of General Purposes; R. Horton Smith, Q.C.; H. F. Frost, Grand Organist; E. Cutler, Q.C., Past Grand Organist; Dr. Balfour Cockburn, Provincial Grand Master of Guernsey and Alderney; Dr. Hugh Mackintosh and Bro. Chas. Martin, Past Assistant Grand Directors of Ceremonies; the Earl of Euston, Provincial Grand Master, Northamptonshire and Huntingdonshire; Alderman Walter Vaughan Morgan; General J. C. Smith, Past Grand Master of Illinois. There were present a large number of medical brethren, including Bros. Reginald Harrison, Henry Morris, Edmund Owen, W. P. Herringham, Samuel West, Arbuthnot Lane, A. A. Bowlby, R. J. Reece, Essex Wynter, Leopold Hudson, Howard Tooth, Alban Doran, W. H. H. Jessop, Bruce Clarke, H. J. Waring, C. A. Parker, Danford Thomas, and F. W. Clark.

The impressive ceremony of the consecration was proceeded with, the Earl of Lathom giving the invocation, while the Dean of Gloucester delivered the oration, and the anthems were sung by Bros. Frost, Kenningham, Fryer, and Stubbs. The Grand Master then constituted the lodge, the following officers being appointed:—Bros. Clement Godson, M.D., P.G.D. (W.M.); Thomas Trollope, M.D., P.G.D. (Acting I.P.M.); Alfred Cooper, F.R.C.S., P.G.D. (S.W.); W. J. Walsham, F.R.C.S., P.M. (J.W.); D'Arcy Power, F.R.C.S., P.M., P.G.J.W. Warwickshire (Treas.); T. G. A. Burns, M.R.C.S., P.M., P.P.G.D. Surrey (Sec.); Walter Gripper, M.B., P.M. (S.D.); Phineas S. Abraham, M.D. (J.D.); G. H. R. Holden, M.D. (I.G.); F. Swinford Edwards, F.R.C.S., P.M. (D.C.); J. H. Gilbertson, M.R.C.S., P.M., P.P.S.G.D. Herts (Stwd.); C. B. Lockwood, F.R.C.S., W.M. 1150 (Stwd.); C. P. White, M.B. (Stwd.); Ernest Clarke, F.R.C.S. (Org.); Madden, Librarian of St. Bartholomew's Hospital (Tyler).

Among the other founders of the Lodge are Bros. W. Haig Brodie, B. Latter Tandy, A. G. R. Foulerton, H. D. Lauchlan, G. H. Forman, J. E. Sandilands, C. A. Parker, A. A. Bowlby, F. W. Clark, W. T. Partridge, J. Pickett, and R. J. Reece.

The first act of the new Lodge was to enrol its first honorary member in the person of the Prince of Wales. The Benediction having been pronounced, Their Royal Highnesses took their departure, and on leaving the hospital received an ovation from the students gathered in the quadrangle. The guard of honour was furnished by the St. Bartholomew's Hospital Company of the Volunteer Medical Staff Corps. The brethren afterwards adjourned to a banquet at the Albion, Aldersgate-street, the toast of "The Visitors" being responded to by General Smith of Illinois.

We wish this new professional lodge every success; it has received a magnificent christening, and the number of joining members is already very large.

A MAHOMEDAN DOCTOR ON THE MECCA PILGRIMAGE.

MUCH has been written concerning the pilgrimage to Mecca, but, as a rule, such writings are somewhat one-sided. Either the writers are Mahomedans who know nothing of the Western exigencies with regard to sanitation, or else they are not Mahomedans, and are therefore out of sympathy with the pilgrims, are not allowed to approach the

Digitized by Google

sympathy of medicine with the work of the epidemiologist. Professor Michael Foster was an especially welcome guest, for his life had been spent in providing a scientific basis for medicine. The presence of Mr. Cope, the chief adviser of the Board of Agriculture, marked the need which the epidemiologist felt in the association of human and animal pathology with the study of epidemic disease; and of Dr. Tatham, the head of the Statistical Department of the State, of the necessity of using the statistics which he provided, and of submitting to the stern test of figures the work upon which the members of the society were engaged. He commented on the support he had always received from Sir Walter Foster in the performance of his official duties.

Mr. Christopher Heath and Professor Clifford Allbutt replied to the toast. Mr. Heath discussed the examination of medical officers of health and dwelt on the excellence of the examination of the united colleges. Professor Clifford Allbutt, referring to the self-denying labours of the medical profession in preventing disease and in thus depriving themselves of the work upon which they as a profession depended for their livelihood, instanced the work of one whose efforts had resulted in the reduction of disease, and especially the abolition of enteric fever from the locality in which he practised, and the consequent reduction of his income.

The President, in proposing the toast of "The Epidemiological Society," commented on the fact that the number of persons who associated themselves for the study of epidemic disease had always been small, but, from the foundation of the society, among those who took part in the proceedings were some of the best thinkers and most distinguished members of the profession, and he alluded to the loss the society had recently sustained by the death of a beloved leader whose own work had largely added to our knowledge of epidemic disease. He then referred to the history of the study of epidemiology, of which the published proceedings of the society were an index. The beginnings of this study were to some extent gropings in the dark, and theories were often formulated which had to give way to the teaching of the facts which were observed. Theory and fact were sometimes struggling against each other, but by degrees the facts were accepted. Scientific epidemiology had thus come into existence and paved the way to a better knowledge of the diseases which attack communities.

Sir Benjamin Ward Richardson, in proposing "The Health of the President," referred to the work in London in which he was engaged, and congratulated him on his recognition of the need for sound and scientific knowledge to be made the basis of the health administration of London.

After a suitable acknowledgment by the President the society adjourned.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Leicester Urban Sanitary District.—Dr. Joseph Priestley in his current annual report has continued his interesting observations on the distribution of enteric fever in Leicester, which he commenced in his 1893 report, and it appears that the 1894 experience led to much the same conclusions as did that of 1893—i.e., it showed a greater incidence of the disease on houses provided with pails, privies, or water-closets with ashpits than upon those provided with water-closets and bins. We imagine, however, that there are some who would object to the classification of houses furnished with waterclosets and ashpits with those provided with pails and privies. Dr. Priestley also gives an account of a localised outbreak of enteric fever comprising 47 cases and thirty-seven houses, which he considered due to the interchange of infected pails. In this account two series of cases are given; in the one, no less than 7 cases were, Dr. Priestley thinks, directly infected from the first case; in the other, 8 cases of the disease were apparently contracted either directly or indirectly from the first. Of the total thirty-seven houses invaded in the outburst 81 per cent. had pails and 18·9 per cent. waterclosets. Dr. Priestley, after discussing the causes to which outbreaks of enteric fever are usually attributable, considers that a thesis of typhoid fever infected pails is the one which best explained the distribution of the disease. Apart from the disuse of pails altogether—which is the course Dr. Priestley advocates—or the return of each pail to the house from which it was taken, it is difficult to devise a remedy for the risks which the pail system would seem to incur. Obviously there must often be in a large town cases of unrecognised enteric fever, and probably in those instances where diarrhœa is a prominent symptom there is considerable danger of infection occurring before the nature of the disease is recognised. As regards the distribution of typhoid fever on pervious and impervious formations, Dr. Priestley observes that the figures for 1894, like those for 1893, show that the greatest incidence of the disease occurred on gravel and sand and the least on clay. The experience as regards diarrhœa in Leicester during 1894 fully bears out Dr. Ballard's classical researches on the relation between the prevalence of this disease and the temperature of the earth at a depth of 4 ft. The registered vaccinations in Leicester for the year 1894 show a considerable falling off on those of the previous year, the respective numbers being 133 and 249. As, however, Dr. Priestley observes, the Vaccination Acts are practically a dead letter, the number of certificates received by the vaccination officer is really little or no criterion of the actual number of vaccinations performed, and many persons have apparently had their children vaccinated by private practitioners. In commenting upon the high death-rate among illegitimate infants Dr. Priestley suggests that the sanitary committee should keep a register of the illegitimate children born in the town, so that any suspicious cause of death might be inquired into; and he also reports that the percentage of uncertified deaths in Leicester has been increasing, while inquests seem proportionately to be decreasing. The proper certification of all deaths should, he observes, be enforced by law. In that section of his report which refers to the fever hospital Dr. Priestley draws attention to the fact that the present small-pox hospital is only a temporary building, providing a maximum accommodation of twenty beds, and he points out that no trouble should be spared to find a suitable site for a proper small-pox hospital well outside the town, so that in the event of small-pox appearing again it may not be necessary to discharge the scarlet fever patients. Dr. Priestley alludes, too, to the necessity of providing a new fever hospital, one that shall be worthy of "a town that, in other municipal and sanitary matters, generally takes the lead." In Part III. of his report the vital and mortal statistics of Leicester are dealt with, but space prevents our touching upon them save to state that the general and zymotic death-rates recorded during 1894 were the lowest chronicled in the annals of the borough.

Eastbourne Urban Sanitary District.—Dr. W. G. Willoughby, in submitting his first annual report as medical officer of health of Eastbourne, gives a detailed account of the borough, describing its site, geology, water-supply, &c. He also enters thoroughly into the age and sex distribution of the population. The water-supply is, Dr. Willoughby states, of excellent quality, save for its hardness, and to remedy this defect he advises its treatment by some such process as the "Porter-Clark." Dr. Willoughby also observes that charges for water-supply to dwelling-houses should be inclusive, so as to embrace baths. In Eastbourne these very necessary fittings are treated as luxuries, and doubtless the visitors to Eastbourne have to pay their share of the charges. The isolation of infectious disease is increasing in popularity in Eastbourne, and the percentage of notified cases isolated during the past three years has been respectively 56·9, 64·5, and 72·9.

Kingston-upon-Thames Urban Sanitary District.—Mr. Beale Collins devotes a considerable portion of his report for 1894 to a discussion of the desirability or otherwise, from a public health standpoint, of the proposed extension of the borough so as to embrace the ecclesiastical parishes of Kingston and Ham. Without following Mr. Collins step by step through his interesting observations, it may be stated that he considers the proposal would tend to produce what he terms a normal community in the matter of age, sex, and class distribution, and that, as far as drainage is concerned, "there is nothing to be said against extension and everything in its favour"; while in regard to isolation accommodation and the control of infectious disease generally, Mr. Collins thinks that much good would result.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6166 births and 3394 deaths were registered during the week ending

Digitized by Google

June 29th. The annual rate of mortality in these towns, which had been 15·4 and 16·2 per 1000 in the two preceding weeks, further rose last week to 16·7. In London the rate was equal to 16·9 per 1000, while it averaged 16·5 in the thirty-two provincial towns. The lowest rates in these towns were 9·6 in Brighton, 9·9 in Derby, 11·5 in Huddersfield, and 11·6 in Portsmouth, Leicester, and Preston; the highest rates were 19·2 in Bolton, 19·4 in Burnley, 21·0 in Salford, 22·8 in Gateshead, and 25·7 in Liverpool. The 3394 deaths included 493 which were referred to the principal zymotic diseases, against 399 and 400 in the two preceding weeks; of these, 177 resulted from diarrhœa, 140 from measles, 59 from whooping-cough, 55 from diphtheria, 32 from scarlet fever, 29 from "fever" (principally enteric), and 1 from small-pox. The lowest death-rates from these diseases were recorded in Brighton, Swansea, Nottingham, Derby, and Wolverhampton; and the highest rates in Cardiff, Leicester, Salford, Liverpool, and West Ham. The greatest mortality from measles occurred in West Ham, Plymouth, Cardiff, Bolton, Manchester and Newcastle-upon-Tyne; from scarlet fever in Burnley; from "fever" in Huddersfield; and from diarrhœa in Croydon, Leicester, Salford, and Preston. The mortality from whooping-cough showed no marked excess in any of the large towns. The 55 deaths from diphtheria included 38 in London, 3 in Liverpool, 2 in West Ham, 2 in Portsmouth, and 2 in Birmingham. One fatal case of small-pox was registered in London, but not one in any of the thirty-two large provincial towns. There were 34 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, June 29th, against 23, 19, and 22 at the end of the three preceding weeks; 25 new cases were admitted during the week, against 5, 2, and 8 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital, which had been 1589, 1637, and 1732 on the three preceding Saturdays, had further risen to 1894 on Saturday last, June 29th; 319 new cases were admitted during the week, against 179, 199, and 251 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 152 and 186 in the two preceding weeks, declined to 160 last week, but were 45 below the corrected average. The causes of 38, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Leicester, Sheffield, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Nottingham, Preston, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·1 and 19·4 per 1000 in the two preceding weeks, declined again to 19·2 during the week ending June 29th, but exceeded by 2·7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·2 in Leith and 15·3 in Paisley to 20·9 in Greenock and 27·4 in Perth. The 566 deaths in these towns included 48 which resulted from diarrhœa, 14 from measles, 9 from whooping-cough, 3 from diphtheria, 3 from "fever," 1 from scarlet fever, and not one from small-pox. In all, 78 deaths were referred to these principal zymotic diseases, against 58 and 76 in the two preceding weeks. These 78 deaths were equal to an annual rate of 2·7 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 25 and 26 in the two preceding weeks, further rose to 48 last week, of which 29 occurred in Glasgow, 6 in Dundee, and 4 in Aberdeen. The 14 deaths referred to measles corresponded with the number in each of the two preceding weeks, and included 6 in Glasgow and 3 in Paisley. The fatal cases of whooping-cough, which had increased from 11 to 20 in the three preceding weeks, declined again to 9 last week, of which 6 occurred in Glasgow and 2 in Edinburgh. The deaths from diphtheria, which had been 3 and 4 in the two preceding weeks, were 3 last week, all of which were recorded in Glasgow. The 3 deaths referred to "fever" were within 1 of the number in the preceding week, and included 2 in Glasgow. The fatal case of scarlet fever occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 87 and 94 in the two preceding weeks, further rose to 99 last week, and exceeded by 18 the number in the corresponding week of last year. The causes of 25, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·1 and 20·1 per 1000 in the two preceding weeks, rose again to 22·4 during the week ending June 29th. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 27·3 per 1000, the rate during same period being 16·7 in London and 18·8 in Edinburgh. The 150 deaths registered in Dublin during the week under notice showed an increase of 15 upon the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 8 and 16 in the two preceding weeks; of these, 5 resulted from diarrhœa, 3 from whooping-cough, 1 from "fever," and not one either from small-pox, measles, scarlet fever, or diphtheria. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 3·2 in London and 1·3 in Edinburgh. The 5 fatal cases of diarrhœa exceeded the number in any recent week. The deaths referred to whooping-cough, which had been 3 and 1 in the two preceding weeks, rose again to 3 last week. The mortality from "fever" corresponded with that recorded in the preceding week. During last quarter 23 fatal cases of small-pox were registered within the city, against 78 in the first quarter of this year. The 150 deaths registered in Dublin last week included 26 of infants under one year of age, and 32 of persons aged upwards of sixty years; the deaths of infants corresponded with the number in the preceding week, while those of elderly persons showed a slight further increase upon recent weekly numbers. Only one inquest case and no death from violence was registered; and 51, or rather more than a third, of the deaths occurred in public institutions. The causes of 16, or nearly 11 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL GREENHILL, retired pay, has been transferred from Lincoln to Guernsey. Surgeon-Major Morgan has been appointed to Woolwich, Surgeon-Major Maclean to Chatham, and Surgeon-Captain Watson to Glasgow. Surgeon-Captain Johnson has been granted sick leave to England from India. The following officers have completed a course of instruction in meat inspection at Edinburgh:—Surgeon-Majors O'Sullivan and Dick, Surgeon-Captain Kiddle, and Surgeon-Lieutenants Barnett and Master. The following officers have been placed under orders to attend a course at Edinburgh:—Surgeon-Lieutenant-Colonel Slaughter, Surgeon-Majors Robinson and Jencken, and Surgeon-Captains Cardew and Davidson. Surgeon-Captain Trask has been selected for duty with the Egyptian army.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant Herbert C. French to do duty with the Coldstream Guards as an attached officer, vice Surgeon-Captain M. T. Yarr, who vacates his post on appointment as physician to the Crown Prince of Siam.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major R. J. Baker (Bombay), Residency Surgeon and *ex-officio* Assistant to the Political Resident in Turkish Arabia, is appointed to officiate as Medical Officer of the 2nd Regiment Central India Horse, and of the Western Malwa Political Agency during the absence on leave of Surgeon-Captain C. M. Moore. Surgeon-Captain A. R. S. Anderson, Surgeon-Naturalist of H.M.'s R.I.M.S. steamer *Investigator*, is appointed to officiate as Superintendent of the Indian Museum during the absence of Surgeon-Captain A. W. Alcock, who accompanies the Pamir Commission as Surgeon-Naturalist. Surgeon-Captain J. B. Smith has delivered over charge of the Shikarpur Prison. The services of Surgeon-Captain W. Molesworth and Surgeon-Captain C. Donovan are placed temporarily at the disposal of the

Digitized by Google

Government of Madras. The services of Surgeon-Major E. F. H. Dobson are replaced at the disposal of the Government of India, Home Department. Surgeon-Colonel H. Cook takes over the duties of Principal Medical Officer, Bombay Command from Surgeon-Colonel C. A. Atkins, A.M.S. Surgeon-Major C. L. Swaine proceeds to England on the recommendation of a medical board in anticipation of the leave which will be hereafter granted to him by the Government.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Arthur Taylor Wear, M.D., 1st Newcastle-on-Tyne Volunteer Artillery (Western Division, Royal Artillery), to be Surgeon-Major. Surgeon-Lieutenant John Hugh Maclean, F.R.C.S. Edin., 2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment), to be Surgeon-Major.

VOLUNTEER CORPS.

Artillery: 2nd Middlesex: Surgeon-Lieutenant J. H. Gibson, M.D., resigns his commission. 1st Cornwall (Duke of Cornwall's) (Western Division, Royal Artillery): Surgeon-Captain W. Mason to be Surgeon-Major. *Royal Engineers:* 1st Gloucestershire: William Balfour Fergusson, M.D., to be Surgeon-Lieutenant. *Rifle:* 4th Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant E. Roe resigns his commission. 1st Volunteer Battalion the Royal Scots Fusiliers: The under-mentioned Surgeon-Majors to be Surgeon-Lieutenant-Colonels: W. Wilson, M.D., and W. Frew, M.D. 6th Volunteer Battalion the Gordon Highlanders: James Taylor, M.D., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Highland Light Infantry: Surgeon-Captain H. St. Clair Gray, M.D., resigns his commission.

THE PARKES MEMORIAL PRIZE FOR 1894.

According to the *Pioneer Mail* of June 12th last, we have to congratulate Surgeon-Major Donald Ross, Madras Medical Service, on having won the Parkes Memorial Prize for his essay on "Malarial Fevers: their Causation and Prevention." We learn, moreover, from the same source that the Maharajah of Patiala, acting on the suggestion of Surgeon-Major Owen, his medical adviser, has applied for the services of a medical officer to carry out an investigation into the fevers which prevail in his State during the rains, and that the Maharajah has named Surgeon-Major Ross for the work. The Durbar are prepared to bear all the expenses of the inquiry, and it is to be hoped that the Indian Government will accede to the Maharajah's request. Fever is of all the diseases of India that which prevails the most extensively and causes the largest mortality among the natives of that country, especially when the soil of certain districts becomes waterlogged. There are several questions of a scientific and bacteriological character respecting the micro-organism of malaria in India requiring thorough investigation, and Surgeon-Major Ross having made a special study of the subject, in addition to having gained the Parkes Memorial Prize, seems to be eminently qualified to undertake such an investigation.

THE MEXICAN ARMY MEDICAL DEPARTMENT.

The *Army and Navy Gazette* says: The Mexican Army boasts of a medical department which is clearly sufficient for the needs of the sick soldiers. The medical officers consist of one brigadier-general, head of the department; one brigadier-general, chief inspector; two colonels, seventeen lieutenant-colonels, fifty-four majors, and twelve lieutenants on probation. Apothecaries: One lieutenant-colonel, two majors, two first-class captains, and five second-class captains. Administrative hospital officials: One lieutenant-colonel, four majors, and five second-class captains. Commissaries: One first-class captain, four second-class captains, and five lieutenants. Medical Staff Corps: One captain, three lieutenants, three sub-lieutenants, sixteen first-class sergeants, twenty-three second-class sergeants, thirty-nine corporals, and one hundred and sixty-eight privates. These figures show 124 commissioned officers to a strength of 246 rank and file.

"THE 'KISSING CASE.'"

The case which has been so frequently alluded to and commented upon by the Anglo-Indian press under the above heading will be in the recollection of our readers. A statement has recently appeared in some of the Madras papers that Surgeon-Major Clarence Smith will be reinstated in the Indian Medical Service provided that he consents to be tried by court-martial and is acquitted by the court of the charges brought against him. Whether this rumour be well or ill founded is more than we can say, but we see no reason for altering the opinion that we formed from the narrative of facts given at the time in the press—viz., that Surgeon-Major Smith had, under all the circumstances, been very severely treated, and that there were, at any rate, grounds for having the matter more fully investigated and reconsidered.

THE UNHEALTHINESS OF OOTACAMUND.

A paragraph in the *Times of India* of the 14th ult. refers to the very unhealthy condition of this favourite station and health resort of the Madras Presidency. For some time past there has been a good deal of sickness in this station, but during the present season the number of sick people at Ootacamund is said to be unprecedented. The prevailing diseases are stated to be throat affections, low forms of fever, and typhoid fever, pointing to the existence of such causes as defective drains and bad water-supplies. Several cases of sickness have occurred at Government House as well as at other parts of the station, and it is alleged that some of the visitors have preferred to return to the plains rather than incur the risk of contracting disease by remaining at Ootacamund.

FEVER AT MOOLTAN.

According to the Indian papers enteric fever has been unusually prevalent of late at this station. Several fatal cases have occurred at the station hospital. The men belonging to the new draft have been sent up to the hills as a precautionary measure and in order to gradually acclimatise them to an Indian climate.

EXAMINATION FOR STAFF-SURGEONS.

An examination of naval surgeons who are eligible to qualify for the rank of staff-surgeons will be held at Haslar Hospital on the 10th inst. Notice should be sent to the Inspector-General not later than to-day (Saturday), July 6th.

SURGEON-MAJOR ROBERTSON.

We are very glad to learn that Surgeon-Major Robertson, who was at the time of the latest intelligence from India staying at Simla, has quite recovered from the wound he received at Chitral.

CALCUTTA.

The Calcutta death-rate, although it has decreased, still remains high—11 per 1000 above the average. Fevers, small-pox, and cholera are unduly prevalent.

DEATH IN THE SERVICES.

We regret to have to announce the death of Surgeon-Captain George Nelis, A.M.S., attached to the Poona District at Bombay, on the 9th ult.

Two officers and eighty-nine non-commissioned officers and men of the Hants Company of the Militia Medical Staff Corps left Aldershot on the 5th inst. for the annual training at Netley.

Correspondence.

"Audi alteram partem."

IS METEOROLOGY A SCIENCE?

To the Editors of THE LANCET.

SIRS,—I have not seen the article in the *Edinburgh Review*, but I have read your interesting notice of it, in which the above question is propounded. As you justly say, if facts be accurately observed and recorded, leading to certain conclusions however slight, the subject investigated deserves to be called a science. At the same time meteorology appears to stand on altogether a different footing from the various branches of scientific inquiry in which mankind is engaged. In every one of these the question to be investigated, whether in the organic or inorganic world, has reference to the position of the subject in relation to its environments. Whether this be an inert mass of rock or an organic substance we seek for the influences acting from without which affect its constitution. We never suppose that a spontaneous change can occur in anything whilst the surrounding conditions remain the same. For this reason, in order to discover the nature of any substance, we submit it to experiments—that is, put it under new conditions.

We know nothing of the characters of objects in this world as existing *per se*, as these depend largely on their surroundings. We ourselves as human beings could have no separate

Digitized by Google

existence from the earth, for, if the normal human body implies the possession of various organs with their tubes and contents, then the lungs with their tubes are included in the idea of a perfect man, and yet the contents of these tubes—the air—are manufactured outside ourselves.

Now as regards meteorology we use different language, we speak of changes originating within the globe itself. It may be true that all that is said about Polar ice and the Gulf Stream is correct, but the question is, Why should the wind blowing from the north into a warmer region produce a cyclone at one time rather than another? Why were the conditions altered which caused it? If we are speaking of any object on the globe and we observe that changes are occurring in it we look for the causes in its environments; we never believe in the possibility of a change without the operation of an external cause. It may be true that the earth is a globe of fire and that we inhabit only a thin cooled crust, and therefore internal conditions are ever present to produce a change, but if we compare the earth as a whole with portions of it, such as we deal with in scientific inquiry, we should naturally look to the earth's environments as the causes of change; now the only variable ones are the position of the planets and the heat of the sun. As regards the former, I believe observers have discovered that their position produces no influence on the earth, and this leaves the varying heat of the sun as the only known external factor to affect us. As far as we know, the conditions of the earth in space are always the same. We know the inclination of the earth's axis, and we should conclude that the seasons would be invariably the same, together with the trade winds and certain other constant phenomena. Why there should be the slightest difference in corresponding days of different years is the puzzle. The causes of uniformity are clear, those of dissimilarity are obscure. My point is that all objects in the world are dependent for their characters, in an unknown measure, on their environments, and that all scientific inquiry has reference to the altered condition of these environments and the observations of the new phenomena thereby produced. Now as regards the earth as a whole we know nothing of its environments (and perhaps never shall), and therefore we cannot study the changes constantly occurring on its surface in the manner we do in various branches of science. It, therefore, may be well asked, Is meteorology in the true sense a science?

I am, Sirs, yours faithfully,

Grosvenor-street, June 29th, 1895. SAMUEL WILKS.

"THE DISCOVERY OF ANÆSTHESIA."

To the Editors of THE LANCET.

SIRS,—As it is a question of considerable historic interest to be settled, I beg leave to trespass a little further on your space to reply to the letter of Mr. W. Rogers Williams in THE LANCET of May 4th, in which he urges the claim of Morton as being the discoverer of anæsthesia by means of ether for prolonged surgical operations. Without doubt there is a vast difference between the discoverer or inventor and the one who popularises or makes widely known the discovery or invention. That has often been demonstrated in the cases of our most noted inventors. The original brain-work generally receives neither the credit nor emolument due to its genius. I take up the historical facts in Mr. Williams' letter and appeal to any fair-minded person to say whether or not all of the credit for the discovery of the anæsthetic properties of nitrous oxide gas is due to Sir Humphrey Davy? That this discovery did not excite general attention resulting in the extensive practical use of gas as an anæsthetic was simply owing to the general stupidity of mankind at that time. Does Wells deserve the name of discoverer of this application of the gas in surgery? He may have made the remark, "A new era in tooth-pulling," after he came from under the influence of the anæsthetic, but Sir Humphrey Davy had out his wisdom tooth painlessly by this means forty-four years before that time, and two years before that Long of Georgia had done his immortal operation under ether narcosis.

As for Wells having "thoroughly grasped the anæsthetic idea," and thus being worthy of laud, it may be stated that the "anæsthetic idea" had been evolved long before Wells' sojourn on our planet; alcohol, opium, hemp, and mandragora were well-known anæsthetic agents, and the "memorable sentence" of our opportune friend, Sir Humphrey Davy, shows plainly enough that he too understood quite well the idea of anæsthesia. It is impossible, likewise, that any man of average intellectual power should fail to appreciate the "far-reaching importance" of a good practical anæsthetic. Nor is the matter of publication in some journal a criterion in discovery, nor should such a standard ever be elevated.[1] Facts are facts whether they be published or not, and in this case we have certain plain cold facts that would tickle the palate of Mr. Gradgrind, were that gentleman capable of any feeling. Granted that "publicity" be the "touchstone of invention," I have proceeded to pour a little of the reagent of truth upon its marred surface, and lo! the tiny glittering streak of precious history appears, as the marks of the base-metal simulations are dissolved. In this metaphor let us put far from us the notion that the touchstone should be anything but a faithful touchstone, giving true reactions. No just man will admit, however, that "publicity" in the sense of energetic publication or widely diffused statements is any proof of right. Too much injustice has already been done by thus rendering imposition easy.

Facts may be piled up as high as the sky as to what Wells did, what Jackson did, and what Morton did, but the plain, unvarnished truth is that Long did the first well-authenticated surgical operation under ether, and that operation was performed in 1842, two years before Wells' tooth was pulled under gas, four years before Morton extracted Eben Frost's tooth by means of ether anæsthesia. It is to be hoped that the gyrations of Wells, Morton, and Jackson will not confuse the perception of the unprejudiced bystander. It is curious to observe the persistent indifference to Long's rights manifested by the standard histories of this subject. And I shall be happy if I live to see his name[2] taken from the depths of fast-thickening obscurity and placed upon its proper ledge, so that the waves of oblivion shall not close over it. It is left to the world and its posterity to measure out the amount of praise to be bestowed upon the discoverer of ether narcosis; nor is it my part to urge that one jot of rightful meed should be taken away. I call for exact differentiation. Give the discoverer his praise and the promoter or populariser his credit, to each such as may be his due. Giving heed to the value of your space and time, I shall not discuss this matter in the future unless, Sirs, you honour me with the signal for another tilt. I shall be glad to see a reply from Mr. Williams, however, as I feel fairly confident that he, at least, will "e'en gang his ain gait" regardless of what has been said to change the general opinion in this matter. With many thanks for your kindness,

I am, Sirs, yours very sincerely,

Lynchburg, Virginia, May 18th, 1895. S. P. PRESTON, M.D.

"THE REMUNERATION OF MEDICAL OFFICERS TO PROVIDENT ASSOCIATIONS, CLUBS, ETC."

To the Editors of THE LANCET.

SIRS,—As this question is in one form or another engaging considerable attention in the profession, it is most important that we should be accurate in our statements regarding it. In THE LANCET of June 22nd Dr. Paget Thurstan makes an elaborate calculation, based upon an assumption of one month's sickness per head per annum, which he states that he has taken from Mr. Neison's statistics. I fear that our great friendly societies would be in a bad way if this assumption were correct. The fact is, Dr. Thurstan has confused the "average duration of sickness per member sick" with the "average number of days' sickness per member per annum," which is, of course, a very different thing. The figure for the latter is as nearly as possible nine days (*vide* Newsholme). In a provident society of 1000 members, each paying 4*s.* per annum, the medical officer would receive £200 per annum. He would have to attend 9000 days' sickness, or 9000 ÷ 365 = 25 members constantly sick; this gives him

[1] In 1668 it became known to Halley, the eminent mathematician, that (Sir) Isaac Newton had discovered the principle of reciprocal attraction gravity which regulated the planetary movements, but such was his modesty that Halley could with difficulty induce him to claim the great discovery, afterwards elaborately embodied in the "Principia."

[2] Dr. Crawford W. Long was not an "English physician." He was born in Danielstown, Madison County, Georgia, Nov. 1st, 1815; died in Athens, Georgia, June 16th, 1875. Educated at Franklin College, Pennsylvania, 1835; University of Pennsylvania, 1839. Practised in Jefferson County, Georgia, and in 1851 moved to Athens, Georgia.—Appleton's Encyclopædia of American Biography.

Digitized by Google

£8 per annum for each such member. In my experience, however, of a mixed provident society—containing men, women, and children—I find that nine days' sickness per member per annum is an excessive estimate, and that six days is nearer the mark—the reason being that in the large friendly societies (in which the members receive sickness pay) it is seldom the case that a man returns to work directly he is fit to do so; in fact, during the last third of his nominal sickness he often has no medical attendance at all. I quite agree with Dr. Thurstan "that it is possible for the profession to form an association amongst themselves," as this has already been done in many places, but that a shilling per member per month will be paid by the British artisan is an expectation which will not be realised for many years. We have to fight the lay societies, run on commercial lines, who want to "sweat" us for their own profit; and in order to do this we must accept the current rates, gradually raising them after we have obtained control.

I am, Sirs, yours faithfully,

Wandsworth, S.W., July 1st, 1895. W. G. DICKINSON.

ROYAL FREE HOSPITAL: THE OPENING OF THE NEW BUILDINGS.

To the Editors of THE LANCET.

SIRS,—As President of the Royal Free Hospital I have the honour to announce that their Royal Highnesses the Prince and Princess of Wales have graciously consented to open the new front building of the hospital on Monday, July 22nd.

The cost of the new buildings and of various other improvements which have been carried out during the past two years amounts to £30,000, towards which sum £24,000 has already been raised.

I now ask your favourable consideration to the appeal of the committee, feeling assured that I may rely upon your generosity to assist them in obtaining the sum of £6000 which is still required to enable them to carry on the benevolent work of the hospital free from debt.

I have the honour to be, Sirs, your obedient servant,

British Embassy, Paris, July 1st, 1895. DUFFERIN AND AVA.

DETENTION IN THE OUT-PATIENT DEPARTMENT.

To the Editors of THE LANCET.

SIRS,—Your interest in the sick poor attending our London hospitals, and your efforts for the success of the annual collections on Hospital Sunday are so well known that I feel sure I may rely upon your sympathy for that vast number of out-patients who daily throng the hospitals. In the *Graphic* of June 15th, beneath a picture faithfully representing the common spectacle at the receiving-rooms of most of the large hospitals, the following occurs: "In the waiting-room, depressing and rather murky looking in spite of its large area of window-glass and its ostentatious air of being well scrubbed every morning, the patients sit awaiting their turn to see the surgeon. They are of many ages and of one class; but the characteristic which is most strikingly common to all is their patience and their quietude." It is the experience of the parochial clergy that the weary hours of waiting to see the physician, or to obtain the medicine after the interview, are a cause of intense mental, and not infrequently, of physical suffering to the patients. Sometimes a mother will have to wait for hours with a sick child in a vitiated atmosphere, and amid most painful surroundings. For many delicate invalids suffering is prolonged in the melancholy waiting-room for four, six, or even eight hours waiting the convenience of surgeons, physicians, and apothecaries. Some come from a distance, while others have to give up a whole day's work and lose a day's wages for an interview of a few minutes. Why has there been so little reform in this direction? Is it that the physicians and surgeons are in league to resent the smallest interference? Or is it that governors or secretaries will not attend to details so minor in their estimation, so important in the eyes of the sufferer and his friends? We clergy are often called upon to defend in public, or in private, the hospital system from the attacks of antivivisectors, sectarians, and ignorant or prejudiced persons, but this is a grievance which has no defence, and will, if continued, alienate the best supporters of our hospitals. Will the authorities consider this matter from the patient's point of view and arrange for patients to attend in batches at various and fixed hours throughout the day? There can be no difficulty in arranging this by means of different-coloured letters for the unendowed hospitals with different hours appointed, and for the open hospitals mere receiving hours being fixed, or different hours arranged for the various London districts.

I am, Sirs, yours faithfully,

St. Philip's Vicarage, Sydenham. A. EDMUND KING.

"THE CAIRO LUNATIC ASYLUM."

To the Editors of THE LANCET.

SIRS,—In common with all who are interested in the medical and sanitary prosperity of Egypt, I am delighted to learn that at last a specialist in lunacy has been placed in charge of the Cairo Asylum, and have no doubt that before Dr. Warnock's two years have elapsed the advantages resulting from the appointment will have become so evident that it will be made permanent.

Notwithstanding her population of seven or eight millions, Egypt possesses one single establishment only for the reception of the insane of all classes; and hitherto, for lack of a competent physician, there has been no attempt to treat the demented patients in accordance with modern scientific methods; but you will, I trust, allow me to say that as soon as the asylum was placed under British control in 1884 an endeavour was made to find occupation for the inmates, so that they should not be obliged "to sit idly on their beds all day." Dr. Sandwith and Dr. Keatinge commenced the reform by instituting workshops on as large a scale as was practicable, and in my time lunatics were "engaged in the garden, laundry, and kitchen," while a few worked as tailors and carpenters, and a good many as matmakers, the latter industry bringing in a small revenue which was expended, by special permission of the Finance Committee, on the purchase of tobacco and other luxuries. Of course, the patients could not be compelled to work unless they chose, and in spite of the allurements of cigarettes and coffee it was impossible to induce the majority to do anything. Many of them, to the best of my belief, were simply incurably lazy, preferring a life of well-fed idleness in prison to hard labour and scanty food outside. I recollect the man who posed as the Mahdi, but never heard of his attainments as a gardener. It will be interesting to learn later Dr. Warnock's views regarding the cause of the wonderful freedom from mental derangement enjoyed by the Egyptian people. There is probably no country in the world where the insane are relatively so infrequent.

I am, Sirs, yours faithfully,

St. John's, Woking, July 1st, 1895. H. R. GREENE.

"CHOREA GRAVIDARUM."

To the Editors of THE LANCET.

SIRS,—I am interested to see from the summary of Dr. R. C. Buist's paper on Chorea Gravidarum, reported in THE LANCET of June 22nd, that the exaggerated statements regarding the mortality of this disease are being corrected. In a paper on this subject published in vol. xxxiii. of the Transactions of the Obstetrical Society of London, 1892, I drew attention to this point, showing that the chief reasons for these conflicting statements seem to be due (1) to the fact that only the severe cases are published, and (2) to the small number of authentic published cases from which conclusions may be drawn. With regard to the causation of maternal deaths, it is necessary to recollect that, owing to the cachectic state of the system, delivery either at term or prematurely is prone to be attended by additional risks, and more liability to septicæmia. The extreme exhaustion which takes place in severe forms of the disease leads to death before the fœtus is delivered. This is brought about by the anæmia, the rapid emaciation occurring in some cases, the intensity of the movements, and in addition the loss of sleep wearing out the already partially exhausted nervous system. In the paper mentioned the indications given for the induction of premature labour are these: (1) where the mother's system is showing signs of exhaustion from the intensity of the movements and the deficiency of sleep, and where a continuance of the pregnant state is dangerous; (2) where mania or a serious mental affection exists; and (3) where grave complications such as heart disease exist. When the literature of the subject is examined so many cases are found described as chorea

Digitized by Google

gravidarum which have no resemblance to the true disease that it would be well for those who are fortunate enough to meet with examples of this malady to publish their cases fully. I have now seen twelve cases of chorea during pregnancy, all of whom recovered. The recurrence of chorea in subsequent pregnancies appears to resemble ordinary chorea in that relapses may or may not be more severe than the first attack. If chorea has occurred during childhood it is more apt to appear in successive pregnancies, and the younger the patient is during the first pregnancy the greater the liability to recurrence.

I am, Sirs, yours faithfully,

F. J. MCCANN.

Welbeck-street, Cavendish-square, W., June 27th, 1895.

"IN THE MATTER OF MR. T. R. ALLINSON."

To the Editors of THE LANCET.

SIRS,—Your report of the case before Mr. Curtis Bennett is so erroneous in view of the shorthand notes before me that I hasten to correct it, with an intimation that the shorthand transcript can be seen at my office. The magistrate held that Mr. Allinson was never entitled to use the letters of L.R.C.P. without the addition of E. or Ed. for Edinburgh, and that L.R.C.P. could in law be used for London only, and on this fined Mr. Allinson. Mr. Muir Mackenzie signified his agreement with Mr. Allinson's counsel (Mr. H. S. Schultess Young) that a medical man's name being removed from the Register did not interfere with his right to practise, and this fact has been expressed by Mr. Justice Matthews in Allbutt's case and Lord Justice Lopes in a subsequent action. The point practically decided by the magistrate was that L.R.C.P. meant of London only, and that a medical man using these letters may be convicted unless he has the London diploma or writes E., Ed., or Edinburgh after them. I venture to think this point is of general interest to the profession, and shall be obliged by your inserting this letter in your next issue. I am, Sirs, yours truly,

B. ALABONE CHEVERTON,
Solicitor for Mr. Allinson.

Essex-street, Strand, W.C., July 2nd, 1895.

DEATHS UNDER ANÆSTHETICS.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 29th one of your Irish correspondents relates a case of death occurring under chloroform in a patient suffering from empyema. I would suggest that, for incision and drainage of the pleural cavity in cases of empyema where the heart is so much displaced by the effusion that syncope is very liable to suddenly occur, a local anæsthetic is advisable. I have repeatedly seen large empyemata freely opened and drained, the skin over the line of incision having been previously frozen with ethyl chloride or anestile. The operation was done in the usual way and a large drainage-tube introduced. The patient from first to last did not complain of pain, nor were there any signs of shock. The operation of thoracoplasty, of course, requires a general anæsthetic, but as it is not an urgency operation there is usually time for the patient's general condition to be so far improved that a general anæsthetic can be better borne.

I am, Sirs, yours truly,

J. H. MARSH, M.R.C.S., L.R.C.P.,
Senior House Surgeon, the Infirmary, Macclesfield.

June 29th, 1895.

"THE MISUSE OF HOSPITALS."

To the Editors of THE LANCET.

SIRS,—As the point raised by Mr. Biddle is important, it may be well to state that our *Hospital Sunday Supplement*, which he quotes, deals with patients, not with attendances. Thus the tables for 1894 were prepared carefully by the authorities of the Hospital Sunday Fund, relate only to patients, and show that 1,383,634 distinct patients were treated in 1894 at the institutions whose names are given. The figures quoted by the preachers are as precise and accurate as it is possible to make them. They have been compiled from official sources, and the detailed tables are in our possession. Something will have been gained by their publication if the medical profession can be got to realise that, including the endowed hospitals, 1,695,276 actual patients found their way to the hospitals and institutions in 1893, all of whom received some kind of treatment. The only qualification of these figures that we know of is the possibility that in some cases the same patient may have attended at more than one hospital during the year.

I am, Sirs, your obedient servant,

THE EDITOR, *The Hospital.*

Strand, W.C., June 28th, 1895.

"DIFFICULTIES UNDER THE INFECTIOUS DISEASE (NOTIFICATION) ACT."

To the Editors of THE LANCET.

SIRS,—Your opinion on the following case will be highly esteemed. I am a young practitioner trying to work up a practice, and am conversant with public health work. A few days ago I notified a case of diphtheria occurring in a woman who had facilities for isolating herself and who preferred not to go to hospital. On calling next morning I found that the medical officer of health, who also practises, had visited my patient, and in addition to making his inquiries and examination of the premises went into all the circumstances of my patient's case, and then, saying he was a medical man (for my patient, not knowing him, was greatly surprised at his questions) asked to examine her throat, which he did. Having learned that he had done the same thing in another case I wrote charging him with breach of professional etiquette and rather ungentlemanly conduct towards me, as he had never even hinted at his intention; adding that I thought it probably due to a want of thought on his part, I could not allow anyone to interfere with my patients in that manner. He did not reply himself, but through the sanitary inspector begs to acknowledge the receipt of my letter and to say he has forwarded it to the council (local, I presume). If the council take up the matter should I decline to meet it on the ground that it is a private and professional matter outside its jurisdiction. And was I not justified in acting thus? I am, Sirs, yours truly,

July 2nd, 1895. PHAGOCYTE.

*** We are not inclined to regard the matter as of private professional concern only; and this because it is the conduct of a public official which is concerned, and because this official has referred the matter to the public authority whom he serves. The writer would do well to make himself fully conversant with the precedents and letters of the Local Government Board relating to this matter which are published in our articles of January and February last, entitled "Difficulties under the Infectious Disease (Notification) Act," notably the second article, issued on Jan. 26th. A communication should then be addressed to the district council in question, such communication to refer to the precedents which are most apt, and the council should be asked whether it is with authority that the action referred to was taken by their officer. Copy of the correspondence should be kept with a view, if need be, of appeal to the Local Government Board for their opinion and judgment.—ED. L.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENTS.)

City Recreation Grounds.

WHAT was begun some years ago as a doubtful experiment has become a great success. One by one the city churchyards are being converted into recreation grounds pleasing to the eye and a great boon to the poorer citizens living near them. A greater contrast than these spots before and since their conversion could hardly be imagined. There are good grounds for believing that this very desirable movement will continue until the old city churchyard, so graphically described by Dickens, becomes a thing of the past.

"Clerical Breakdown."

Sir Dyce Duckworth's paper and the annotation in the last issue of THE LANCET possess much local interest, the name of Duckworth being very familiar in Liverpool, while the subject of his lecture is brought very prominently before the local

Digitized by Google

profession and the public by paragraphs announcing the fact that the Rev. —— has been ordered by his medical advisers to take several months' holiday, and that he has gone to the Canaries, the Mediterranean, or on even more distant voyages. The return of the reverend gentlemen from these travels to their sphere of duty is also duly chronicled, the rest and change being generally of great benefit. It is quite within the recollection of middle-aged men that a clergyman would have thought himself very hard-worked indeed had he been left to take two full services by himself on Sunday. The Rev. Charles Honeyman sighed when invited by Colonel Newcome to breakfast at nine; what would he have thought of services at eight or even an earlier hour followed by morning, afternoon, and evening services every Sunday, with daily services and frequent sick calls? The architecture of many local churches is rather behind date, and the lofty pulpit in which the preacher is subjected (especially in the evening) to an over-heated and vitiated atmosphere must be very trying to the health.

Grave-plots in lieu of Vaults.

At the seventeenth annual meeting of the Church of England Burial, Funeral, and Mourning Reform Association, which was held on Wednesday, June 26th, in Stafford House, London, by permission of the Duke of Sutherland, the report for the year was read. In this report the thanks of the society are rendered to Mr. F. W. Lowndes of Liverpool for suggesting that grave-plots be substituted for vaults, burial in a grave-plot being the only mode which really meets the wishes of those who desire to rest together in death. A vault becomes full, to the disappointment of the survivors, and a new vault, probably in another place, must be provided; whereas a grave-plot of sufficient length and breadth, surrounded and separated from the adjoining earth by coping, might contain the remains of families for generations if the practice be adopted of "side-by-side" burial in perishable coffins at reasonable distances of time. Such plots might be made small gardens, a tree planted, and flowers grown from year to year to tell of a joyful resurrection.

July 3rd.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Dr. Niven's Report for the First Quarter of the Year.

LAST winter was so exceptionally severe that a few facts, taken from Dr. Niven's summary of the weather, may well be noted. The mean temperature for the thirteen weeks was 4·4° F. below the average for the first quarters of the last ten years. There was much less than even our usual poor allowance of sunshine, the Jordan's Photographic Recorder in Oldham-road registering ninety-nine hours, which period only equals 11 per cent. of its possible duration. The average amount for the quarter during the previous three years was 164 hours. At the Stonyhurst Observatory the amount for the quarter was 210 hours and its proportion 23 per cent. The only factors likely to cause this difference are the sparseness of the population and the absence of manufacturing smoke at Stonyhurst. No doubt the severe cold caused increased smoke from household fires, which would add to the dark cloud above, but one manufacturing chimney equals in smoke production that of very many private dwellings, as evidenced by the immensely greater density of the fumes sent forth. The mean height of the barometer was 29·841 in., being practically identical with the average in the corresponding periods of the previous five years. The amount of rain measured at the City Observatory was 6·848 in., being about half an inch above the decennial average for the quarter. January was marked by squally weather with much rain and snow, becoming colder as the weeks passed by. The mean temperature was 33 6°—i.e., 5·7° below the average of the corresponding period of the previous ten years—the coldest day being the 28th, when the mean temperature was 25·0°. During the month we had twenty-two hours of sunshine—at Stonyhurst there were sixty-three hours—but our twenty-two hours were above the average of January, which for the last three years has been nineteen. February was colder even than January, the mean temperature for the four weeks being 31·5°, which is 7·9° below the average for the month during the previous ten years. On the 6th—the coldest day—the mean for the twenty-four hours was 22·4°. The mean height of the barometer was 30·130 in., being higher by 0·148 in. than the average of several years. Very little rain fell, and we had forty-three hours of sunshine in the four weeks, while the average for the month during the last three years was thirty-seven hours. Frost occurred on twenty-six days. In March the weather became rapidly milder, but there was very little bright sunshine. Rain fell on eighteen days of the four weeks to the aggregate amount of 3·181 in., being nearly 1·5 in. above the average. The mean temperature for the month was 42·3° which is slightly higher than the average and nearly 11° above that of February.

Births.—During the thirteen weeks of the quarter 4791 births were registered in the city, equalling an annual rate of 36·5 per 1000 of the population.

Sickness treated at the public expense.—The cases treated at the public hospitals and dispensaries were 12,030, an increase of 1678 as compared with the number treated in the first quarter of 1894.

Infectious sickness.—665 fresh cases were notified, against 1025 in the preceding quarter, and 820, the average for the first quarters of the previous three years. Small-pox was absent during the whole of the quarter. Scarlet fever was rather more prevalent than is usual, the notified attacks equalling an annual rate of 3·17 per 1000, the average being 2·96. In the last quarter of 1894 the rate was 5·57. Diphtheria was less prevalent than usual, the reported attacks being equal to an annual rate of 0·87 per 1000. Enteric fever also was less prevalent than usual. It is curious that there was less scarlet fever and enteric fever in the old townships than in the other and more salubrious districts of Manchester. The mortality returns indicate a greater prevalence of measles and fewer cases of whooping-cough than we generally have in the quarter. Influenza again visited Manchester during this quarter, 2 fatal cases occurring in January, none in February, and 106 in March. Since then it has been declining, but it has not yet left us.

Deaths.—These, influenced no doubt by the low temperature, equalled a corrected annual rate of 26·8 per 1000 of the population at all ages estimated to the middle of the year, which is more than 9 per cent. above the mean rate for the quarter. In the old township the rate was equal to 37·6 per 1000, in North Manchester it did not exceed 20·4, and in South Manchester it equalled 24·0 per 1000. The Manchester rate exceeded that of the thirty-three great towns by 1·6 per 1000. In London the death-rate was 26 0, in Edinburgh 30 5, in Glasgow 34·8, and in Dublin 37 1. The rate of infantile mortality was 165 per 1000 during the quarter, against 168 in the first quarter of 1894, and ranged from 138 in North Manchester to 208 in the old, or Manchester, township, this high rate telling plainly of bad sanitation and a degraded social and moral condition.

Dr. Niven again expresses his regret that in Manchester, with more than 500,000 inhabitants, so few direct complaints are made to him on matters concerning the public health—only sixty during the three months. The people themselves are apparently indifferent, but they owe a deep debt of gratitude to the Chief Constable and the police for the 2024 separate informations given to the medical officers of health during the quarter.

Degree Day, Victoria University.

On the 29th ult. a large assemblage took place in the Free Trade Hall to witness the conferring of degrees. The Vice-Chancellor, Professor Ward, presided, and was supported by the Principals of University College, Liverpool, and Yorkshire College, Leeds. He said that the annual statement was a plain record of steady progress, and spoke of the University having now "definitely made good its title to a place of its own among the chief educational institutions of the kingdom," and of the impress which time had already left in the death, at the beginning of the session, of Dr. J. G. Greenwood, the first Vice-Chancellor and late Principal of the Owens College, and within the last few days of Professor W. C. Williamson. To the memory of both he paid a graceful and touching tribute. The candidates presented for degrees numbered 118. In June, 1894, there were 115 and in June, 1893, ninety-one. Among them were a Doctor of Science and five Doctors of Medicine. Professor Ward said he had no doubt that the number of graduates in the faculty of medicine during the present session would make possible an equally favourable comparison, although for this the results of the July examinations would have to be awaited. He also mentioned the fact that the Victoria University has been included among the universities at which selected candidates for the Indian Civil Service are allowed to pass their probation.

July 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Mr. Gladstone's Farewell to Midlothian.

AT a meeting of the Midlothian Liberal Association held in Edinburgh on Wednesday afternoon last Mr. Gladstone's formal letter of farewell to his constituents was read. Such a communication can hardly be treated as a matter of politics purely, much less as a matter of party politics, by the most prejudiced of partisans. And to our profession it has a special interest, being the closing scene in a career of unexampled endurance. For sixty years Mr. Gladstone has been in the van of his party, ever contesting, pleading, conciliating, proselytising, and leading, and it is impossible to estimate the strain upon even his physical system that this perpetual intellectual restlessness, coupled generally with no light demands upon his bodily strength, must have been. Yet at the advanced age of eighty-five he remains the possessor of a physique that many a young-old man of forty might envy him. Politics purely apart, Mr. Gladstone must always be an object of respectful interest to the medical man as a remarkable example of a perfect combination of the highest intellectual and physical qualities.

Edinburgh Royal Infirmary.

The much-talked-of enlargement of the buildings of this institution has at last got one step forward, as the managers at their last meeting have adopted the report of a commission appointed to consider certain questions of rebuilding.

The Harveian Festival.

The Harveian Festival took place at the buildings of the Royal College of Physicians of Edinburgh on Friday last, June 28th, when Dr. David Yellowlees delivered the annual oration.

Sir Henry Duncan Littlejohn.

The announcement that Her Majesty has been pleased to grant to Dr. Henry Duncan Littlejohn, the medical officer of health of Edinburgh, the honour of a knighthood has been received with general satisfaction, not only by the friends of the recipient of the honour, but by the inhabitants of the city over whose public health he watches untiringly.

The New Secretary for Scotland.

The appointment of Lord Balfour of Burleigh to be the new Secretary for Scotland will be learned with more interest than usual by medical men, as his lordship is the sponsor of the Midwives Registration Bill. Lord Balfour is a Scotch representative peer, and therefore in possession for a term of a seat in the House of Lords, and has been Parliamentary Secretary to the Board of Trade.

July 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Workhouse Hospital Reform.

UPON June 25th a deputation organised by the Irish Medical Association waited upon the Irish Local Government Board to consider the subject of workhouse hospital reform. The deputation, which was received by Mr. George Morris, the Vice-President of the Board, and Mr. H. Robinson, consisted of the following members: Dr. Henry Oulton, chairman of council; Dr. Arthur Benson, secretary of council; Dr. Jacob, secretary of association, as representing the Irish Medical Association; Dr. Walter Smith, president; Mr. Andrew Horne, vice-president, as representing the Royal College of Physicians of Ireland; Dr. Thornley Stoker, president; Dr. William Thomson, vice-president, as representing the Royal College of Surgeons in Ireland; Dr. James Little, president, as representing the Royal Academy of Medicine in Ireland; and Drs. Moorhead (Cootehill), Wilson (Castleblayney), and Lesper (Rathdrum), representing the workhouse medical officers. There were no reporters but it was expected that the result of the conference would soon be made public.

Trinity College, Dublin.

Dr. Charles Ball has recently been appointed University Anatomist and Dr. E. H. Taylor University Examiner in Anatomy.

Ulster Medical Society.

At the annual meeting of the above society held on June 27th the following were elected office-bearers for the session 1895-96:—President: Professor Sinclair. Vice-Presidents: Dr. Bingham and Mr. Mackenzie. Honorary Treasurer: Dr. Kevin. Pathological Secretaries: Dr. Lorrain Smith and Dr. Lynass. Librarian: Dr. Shaw. Secretary: Dr. McKisack. Council: Dr. Lindsay, Dr. McCaw, Dr. Dempsey, Dr. Calwell, Dr. Bigger, and Dr. McDonnell. It was decided that during next session the meeting shall be held at 8.30 P.M. instead of at 4 o'clock.

The Ballymacarrett "Mystery."

On Friday, June 28th, an inquest was held in Soldierstown, near Moira, county Down, in reference to the death of a woman named Robinson, regarding whose decease some ridiculous rumours had been put in circulation through certain parts of Belfast. As the coroner (Dr. Mussen) stated in opening the inquiry, the deceased died on May 11th, and she was certified as dying from a certain disease; but rumours occurred among the relatives that the real cause of death was not what was certified by the medical men who attended her, and these coming to the ears of the authorities, they deemed it right that the matter should be cleared up and for ever set at rest in connexion with the death of the deceased. The coroner regretted that these suspicions had not been mooted earlier to the authorities, as it was now seven weeks from the woman's death; but he thought it was better they should be cleared now, both for the satisfaction of the relatives as well as of the medical men in charge of the case. From the evidence it would appear that Margaret Robinson, a young married woman twenty-seven years of age, living in Ballymacarrett, Belfast, gave birth to a male child on May 4th, the infant being born when Mr. Cathcart arrived. She went on quite satisfactorily until about eight o'clock in the evening of the second day, when in consequence of a message he paid her a visit (he had already seen her in the forenoon of that day) and found her in pain and vomiting, and on examination he detected a swelling on the right side. Looking upon her case as serious, Mr. Cathcart thought it advisable to have another opinion, and a neighbouring medical man, Dr. Smylie, was called in. After examining her they satisfied themselves that the uterus was empty, but that she had a tumour, and that as far as her confinement was concerned she was suffering from no ill effects from it. They then asked that another medical man should see her, and Dr. Campbell was brought in consultation. He agreed with them that there was a tumour, and told the husband that an operation would be necessary on an early day if there was any prospect of saving her life, and urged her removal to the Samaritan Hospital. Her husband declined to take this course, and Dr. Campbell retired from the case. The woman getting no better, Dr. Darling of Lurgan, who knew her and her friends, as they had come from his neighbourhood, was next brought to see Mrs. Robinson on Tuesday, May 7th, with Mr. Cathcart. He agreed with the diagnosis already made, and recommended the woman's removal to a hospital. The relatives said they thought a child was left in the uterus, but he assured them that there was nothing of the kind. Finding that his wife was getting no better, the husband at last had her removed to the Samaritan Hospital on Tuesday, May 7th, but on condition that no operation was done without his consent, and on Saturday, May 11th, she died in that institution, the husband not having given his consent to an operation being performed. Dr. Campbell was most anxious for a necropsy and recommended the husband to allow this to be made, and pointed out to him how dissatisfied he (Dr. Campbell) was that he had not been allowed to treat the patient in the way all the medical men had agreed was right. The husband asked Mr. Cathcart for a line to enable the body to be taken to Soldierstown, and after the medical man found that he (the husband) was averse to a necropsy being made he did so, but he also wanted a post-mortem examination. The woman's husband taunted Dr. Cathcart in reference to the certificate, remarking that if he knew what was the cause of death there was no reason why he should not give a certificate. When the husband asked Dr. Campbell for a certificate on the evening of the day his wife died, he declined, as he naturally wished the matter cleared up by a necropsy. This, however, as I have said, was refused, and when the husband returned to Dr. Campbell on the day he had buried the body he (Dr. Campbell) gave

Digitized by Google

him the usual certificate to the effect that the primary cause of death was an abdominal tumour, and the secondary peritonitis. After the woman had been buried the people in the district began to talk; all sorts of rumours prevailed, and one of the most ridiculous was that there was a second child undelivered. Finally, the authorities in Dublin decided to hold an inquiry, and they instructed Dr. Macan to make a post-mortem examination. Accordingly Dr. Macan (the body having been exhumed) examined the remains on June 25th, and found the uterus empty, but there was an ovarian tumour of the right side with a twisted pedicle. There was not much peritonitis, Dr. Macan said, but possibly hæmorrhage; but the tumour was ruptured, and, in his opinion, the rupture of it caused death. The uterus was healthy; there were no remains of a child, and he thought an operation would have been the proper treatment, not in a little back room or kitchen, but in a hospital. A juror having asked what led to the inquiry being held, the coroner, producing a bundle of papers, replied that if he had read what they contained he would understand the matter. There was enough in them to hang a man. The medical men, however, he said, would leave that court without a stain on their professional reputation. One of the solicitors in the case, who appeared on behalf of Mr. Cathcart and Dr. Smylie, asked the coroner for copies of the depositions already sworn in the case, but the police authorities objected, saying the more regular way would be to apply for them elsewhere, and the coroner declined to give them. At the conclusion of the evidence the jury found "that Margaret Robinson died on Saturday, May 11th, 1895, at the Samaritan Hospital, Lisburn-road, Belfast, from natural causes—viz., the bursting of an ovarian tumour. The jury are of opinion that every care and attention was given to the deceased by the medical men who attended her." Thus has ended an inquiry in the complete vindication of the professional character of all the medical men concerned in the case. The only pity is that the jury did not add a rider to the effect that those were blameworthy who refused their consent to an operation.

The Queen's College Professors.

Mr. Rentoul, M.P., having forwarded to Mr. John Morley, M.P., a memorial signed by all the Ulster Unionist members and by a dozen Nationalist members, referring to the cases of Professor Meissner of Belfast and several other professors of Queen's College whose salaries had greatly decreased owing to the abolition of the Queen's University, Mr. Morley replied that the question had already been dealt with by their Lordships of the Treasury under a former Government, and on several occasions, and that after very careful consideration they did not feel able to grant compensation in such cases. Mr. Morley also stated that the question was tested by Professor Pye, M.D. Irel., of Queen's College, Galway, by means of a petition of right, and that the case was decided against him with costs.

Belfast Dispensary Committee.

At a meeting of this committee held on July 1st, Mr. Dundee resigned his position as medical officer of the Carnmoney district. His successor is to be appointed at the next monthly meeting.

The Listowel Guardians and the Irish Medical Association.

At the last meeting of the Listowel guardians the chairman, Mr. M. J. Nolan, J.P., delivered a very able and exhaustive speech, in which he contended that the strictures of the Irish Medical Association with regard to the management of union hospitals could not apply to the Listowel union. He compared the dietary of twenty years ago with that of to-day, and showed that whilst in 1875 seventy-three hospital patients got only thirty-three pounds of meat and twenty-four quarts of milk as extra diet, last week in their hospital 110 patients got 245 pounds of meat, 438 quarts of new milk, and 2408 eggs, besides bread, skim-milk, and tea. With regard to bedding, they had wire-woven spring bedsteads with fibre mattresses. "Nothing could exceed the cleanliness of their well-ventilated hospitals and the anxious care with which the wants of the sick poor therein were attended to by the medical officer, the sisters, and the attendant nurses in charge." A most remarkable reduction had also taken place in the death-rate amongst all the inmates of the workhouse: twenty years ago it was very nearly double what it is at present. The statement of a witness before the Financial Relations Committee that some of the Irish unions are mismanaged financially was also animadverted on by the chairman. He admitted that the rates in Listowel union had gone up enormously during the past twenty years. They are now 2*s.* 10*d.* in the pound as against 1*s.* 2*d.* twenty years ago—in other words, for every £1000 of poor's rates then levied they now required more than £2400. But many things tended to produce that result. For instance, expenses connected with Registration, Jurors, and Voters Acts, &c. were now levied off the poor's rates, and in addition to that the actual amount of poverty to be relieved has greatly increased during the past twenty years. This latter state of affairs he mainly attributed to emigration, which, he asserted, results in the vigorous and strong leaving the country, whilst the weakly, the very young, and the very old remain behind a burden on the rates. The guardians were so pleased with the chairman's statement that they decided to have it printed and circulated.

The Limerick District Lunatic Asylum.

A committee of the board of governors of the Limerick Lunatic Asylum last Thursday met the two medical inspectors and the engineer of the Board of Control for the purpose of conferring with them as to the best means of enlarging the accommodation of the asylum. As the result of the conference, the committee decided on recommending that a detached building shall be erected as a hospital for acute cases, and capable of receiving 150 patients. It is also proposed to erect a new residence for the medical superintendent, and the committee further suggest that thirty additional acres of land should be purchased for farming purposes.

Cork District Lunatic Asylum.

Upon the resignation of Mr. G. B. Wilson of his post as assistant medical superintendent on the ground of ill-health, the governors of the institution unanimously resolved to recommend the Board of Control to grant him the largest pension in their power.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

International Statistics.

THE question of the depopulation of this otherwise highly favoured country is continually coming to the fore, and the seriousness of the situation was placed *en évidence* the other day at the Conférence Broca of the Société d'Anthropologie by M. Chervin, who gave the following figures:—

Number of married of both sexes per 1000 inhabitants aged above fifteen years.

Hungary	91·6	Holland	49·0
German Empire	53·0	France	45·8
England	52·6	Belgium	41·9
Denmark	52·0	Greece	41·6
Austria	51·3	Scotland	40·9
Italy	50·1	Switzerland	40·8
Finland	49·2	Ireland	23·0

The other table given by him is still more suggestive:—

	Legitimate living children born per 1000 women aged between 15 and 50 years.	Illegitimate living children born per 1000 women aged between 15 and 50 years.
German Empire	270	26·5
Scotland	269	19·9
Belgium	265	19·8
Italy	251	24·6
England	250	12·1
Austria	250	44·4
Sweden	240	(?)
Ireland	240	4·1
Switzerland	238	10·2
France	163	16·7

The position of France at the very bottom of the list must provide food for painful reflection to the thinking Frenchman, for it means that sooner or later this country will become politically and socially a *quantité négligeable*. How can we account for this inferiority on the part of France? M. Rochard[1] incriminates alcoholism. He says that the consumption of alcohol has in this country doubled within the last twenty years. In 1885 the annual consumption was 1,440,342 hectolitres, whereas the latest statistics give 2,476,387, or no less than 6 litres 45 centilitres per person per annum. In like manner insanity has within the last few years increased one quarter, and the Conseil Général has just voted 4,000,000

[1] Académie de Médecine, June 25th.

Digitized by Google

francs for the construction of a Ville-Evrard of special pavilions to accommodate 700 male and 200 female alcoholic patients. Every visitor to this city must be struck with the prodigious number of wine shops existing. In 1890 there were no fewer than 29 583, or one for every three houses and eighty-two inhabitants. It is, however, very strange that in the discussions that so frequently occur on this subject of depopulation no mention should be made of the chief cause—viz., the Frenchman's innate thrift. There is nothing he dreads so much as poverty for his children, and he consequently is careful not to have too large a progeny. The urban Frenchman, moreover, marries late in life, and the recognition of that baneful institution—concubinage—must be held in great part responsible for this. The crushing expense of a residence in Paris must also act as a deterrent to marriage. The average Frenchman never dreams of emigrating, his reply to any such question being, "Pourquoi m'en aller aux colonies; on est si bien en France."

Hospital Ship for Newfoundland.

It will be a matter of surprise to your readers to learn that floating hospitals are things of the future in a country possessing such an extensive seaboard as France. It is announced that the first of the hospital ships of which the fleet of the *Œuvre de Mer* will be comprised will shortly be put on the stocks at St. Malo. It will be a vessel of 300 tons and will leave France for the fisheries of Newfoundland in March, 1896. The Breton fishermen who pursue their calling in these latitudes will doubtless greatly appreciate this attention on the part of their stay-at-home compatriots.

Hospital Charges.

When a patient is admitted into a Paris hospital a certain daily charge is made unless he be in such poor circumstances that payment is out of the question. A recent prefectorial edict fixes these charges as follows:—Daily charge for adults: medical wards, 3 francs 30 centimes; surgical and lying-in wards, 5 francs. Children: medical wards, 2 francs 80 centimes; surgical wards, 3 francs 50 centimes.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The New "Regolamento d'Igiene."

PROFESSOR PANIZZA, who, as I stated in a previous letter, has been compiling for the Roman Giunta a "Regolamento Locale d'Igiene," has just submitted it to the authority in question. It is divided into five heads. The first deals with "assistenza medica" and "vigitanza sanitaria," and makes ample provision for the effective carrying out of both. It concerns, in fact, the *personnel* of local sanitation, while the second head has reference to the hygiene of the soil and the dwelling-house, particularly to everything affecting the purity of the water-supply as distributed through pipes, by wells, or by fountains. Under the third head cognisance is taken of the foods and drinks. These are to be safeguarded by a series of stringent conditions, controlled by inspectors, as to soundness and freedom from adulteration. The fourth comprises the measures adopted against the diffusion of infective maladies in man and animals and formulates the rules to be observed in "denunzie" (complaints) and disinfecting procedure. The fifth and last head deals with the "polizia mortuaria" (disposal of the dead). The new "regolamento" is a great improvement on its predecessors in simplicity and working. That which was previously in force contained as many as 591 sections, which even then were not exhausted, and from their confusion and complexity were more frequently honoured in the breach than in the observance. The "regolamento" now submitted by Professor Panizza under its five headings and in its whole *ensemble* contains less than a third of its predecessor's sections, with corresponding distinctness in defining the powers and responsibilities residing both in the officials and in the public. Henceforth evasion of the law will be difficult, if not impossible, on the part of the latter, and dereliction of duty on the part of the former will be easy of detection and promptly made subject to discipline. The sanitary procedure of the next few months will put the "regolamento" to the required test; and we shall then have practical proof of the superior conditions under which the health and comfort of the lieges in Rome and its provinces are protected and ensured.

Barbers and Contagious Disease.

A curious case has recently been before the Turin law courts. According to the official report a gentleman, on getting shaved at the barber's whose shop he "frequented" for that purpose, received a slight and involuntary incised wound, the result of which, after a few days, was the appearance of a cutaneous eruption which, when subjected to the examination of the consultants at the local policlinico, was declared to be syphilitic. The razor, it was held, had by a previous performance on the beard of a customer been infected with the malady and caused the characteristic eruption in the next comer, who was the complainant. The court, in punishment of the barber's negligence in cleaning his instruments, fined him 250 lire (£10). The occurrence has excited much comment here as well as in other cities of the kingdom. The public, particularly the travelling public, are apt to turn in at any barber's for shaving purposes, and these functionaries, it is remarked, are far from rigid in their observance of the good English custom of plunging the razor after each performance into boiling water. The matter has been under the consideration of the sanitary office, and henceforth, it is expected, every barber will be compelled to pass his razors through a solution of sublimate (1 in 1000) so as to destroy the infective microbes. Nor is it the razors only that should be thus vigilantly looked to. The combs and brushes of the Continental Figaro are, often after very promiscuous use, seldom as clean as ordinary prudence prescribes—another source of danger to the unsuspecting traveller, particularly in Southern Europe.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Effect of Compressed Air on the Health of Workmen.

DURING the last few months a regulating lock weir has been in course of construction on the Danube Canal, the bottom of the water being made accessible to the workmen by means of submerged iron caissons, into which air is forced so as to displace the contained water. The men in the caissons work under a pressure of four and a half atmospheres, and in consequence suffer from peculiar symptoms, which have been investigated in the clinic of Professor Schrötter. Last Saturday a man died after some hours' work in a caisson, and the post-mortem examination, performed by Professor Hofmann, showed fluid in the larynx and air passages and extravasations into the brain, pharynx, and lungs. Death was due to suffocation from œdema of the lungs and gradual poisoning by carbonic acid. Respiration is retarded by the compressed air, for the red blood-corpuscles absorb an excessive amount of oxygen, and expiration is rendered more difficult. The contents of the superficial bloodvessels and lymphatics are driven inwards, the internal organs are overfilled with blood, the action of the heart and the circulation of the blood are retarded, and general distress, palpitation of the heart, headache, giddiness, and bleeding from the nose, mouth, ears, and lungs ensue. The compression of the muscles and nerves also produces arthralgia. The dangerous symptoms usually show themselves when the man on ceasing work passes from the compressed air in the caisson to the normal atmospheric pressure, the red blood-corpuscles then giving off the excess of absorbed oxygen, which forms gaseous vesicles in the blood, causing obstruction of the vessels, and thereby producing paralysis of the legs, arms, rectum, and urinary bladder. Professor Schrötter recommends as precautionary measures that elderly men or those who are in weak health should not be employed in this work, that the condensation of the air should be gradual, and that the time for working should be short (three or four hours a day). The Council of Hygiene has requested the eminent hygienist, Professor Max Gruber, to prepare a report on the subject, and it will be the duty of the Government to take such means as may appear to be necessary in the interest of the workmen.

True Gonorrhœal Cystitis.

A paper on the above subject was read by Dr. Wertheim at a recent meeting of the Vienna Medical Society. Hitherto the existence of a true gonorrhœal cystitis has not been satisfactorily demonstrated, for disorders of the urinary

Digitized by Google

bladder occurring in consequence of gonorrhœa have been explained by an inflammation localising itself on the internal orifice of the urethra (urethro-cystitis). Some two years ago Dr. Wertheim had under his care a girl aged nine years, who was affected with vulvo-vaginitis in consequence of rape, and whose urine contained leucocytes charged with gonococci. An anæsthetic having been administered, a part of the mucous membrane of the urinary bladder as large as a millet seed was removed, which on microscopical examination showed gonococci in both epithelium and connective tissue. In the submucous connective tissue the capillaries and blood-vessels were found to be filled with gonococci partly involved, partly characteristically tinged. The occurrence of red blood-corpuscles proved that those vessels are to be regarded as capillary vessels and precapillary veins. Gonococci may enter the blood either indirectly through the lymphatic system or by direct penetration into the blood stream at the place of the primary patch. This explains the origin of gonorrhœal endocarditis and other gonorrhœal sequelæ.

Increase of Venereal Disease in Budapest.

According to statistical returns made by Dr. Marschalko, the number of venereal cases in Budapest has doubled since 1887. He supposes the insufficient regulation of prostitution to be the reason of this increase. Well-known prostitutes have hitherto been examined in their own lodgings by the police physicians twice a week; but at the end of 1893 there were 1131 prostitutes and only 14 police physicians; each physician, therefore, had to examine more than 100 prostitutes daily. Dr. Marschalko advocates the microscopical examination of the secretion of the genitals and ascribes the spread of the disease to the circumstance that women affected with syphilis are not allowed to remain in the hospital until their entire recovery. There are also a great many loose women not officially registered. In the clinic of Dr. Róna, among 140 patients there were 58 prostitutes.

The Antitoxin Treatment.

By order of the Hungarian Minister for the Home Department, Dr. Torday has performed 62 curative and 560 prophylactic injections in the district of Békés. In the former group seven children died. Among the children for whom injection was performed as a precautionary measure not one has fallen ill, although sixty-six of them were brought in contact with cases in an infectious stage.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Tourist Season.

THE winter months from November to April are tempered, socially and financially, by the inpouring of European visitors in search of health, amusement, and sunshine. Ten years ago the numbers were hardly worth counting, and consisted chiefly of friends of the English army of occupation. Five years later the tourists reached an aggregate of 4000, and were nearly all English, though Americans had even then begun to include Egypt in their feverish treadmill round the world. During the winters of 1892 to 1894 the numbers were again raised to 5400, and it almost seemed as if a zenith had been reached, for in Cairo, where all the visitors take a more or less temporary rest, two hotels were obliged to close their doors for want of guests and money. But in the season just concluded there were no less than 7492 arrivals into the country either by way of Alexandria or by the Suez Canal, and of this unheard of number only 45 per cent. were English, 45 per cent. were American, and the remaining 10 per cent. were made up by German and other nationalities. The Americans themselves pretend that this great impetus from their country is a good deal due to the Cairo exhibit at the Chicago Fair. For next winter we are promised another bumper season, and some of the hotels are already building extra accommodation. Last winter lent itself kindly to the future development of Egypt, for it was exceptionally rainless, and though the temperature on the night of Jan. 6th fell to the unprecedented minimum of 32° F., and again on Jan. 19th to 35°, occasioning the death by frost of many astonished vegetables and flowers, the winter months passed away very pleasantly and have been followed by a very cool spring.

Anti-diphtheritic Serum.

The report of the Alexandria Committee formed in October last states that between November and May forty-four cases of diphtheria have been treated by serum obtained from Dr. Roux. Thirty-three patients recovered and eleven died, and tracheotomy was performed four times, with one death. To provide for the future wants of Alexandria and possibly some outlying towns of Egypt, two horses have been immunised and will supply serum in abundance. Great credit is due to our Greek colleagues, who are chiefly responsible for this item of progress. The Greek hospital lent a bacteriological laboratory, and a site for a special stable. One of the horses was bought by the committee, and the other was presented by the two Princes Toussoun. This is almost the first time that any of the Royal household have taken any intelligent or philanthropic part in the direction of science or medicine. In Cairo the serum from France or Germany is to be found for sale at all the chief druggists' shops, and is also sold by the Sanitary Department.

The Medical School, Cairo.

It is now five years since the first European was appointed to this school as Professor of Anatomy. During the past year fresh attempts have been made to emerge from darkness into light. A German has been appointed as Professor of Pharmacy and Materia Medica. Dr. Kaufmann is now to be Professor of Bacteriology, and is having a laboratory furnished for him, and a European librarian and secretary has taken the place of an Egyptian. Many important changes must still gradually be made, though in addition to French jealousy every proposal for reform is met by obstinate obstruction on the part of some of the higher native officials. Their fear of being ousted entirely by Europeans would seem to be premature, for the following branches are still exclusively taught more or less badly by native medical men—physics, natural history, physiology, histology, operative surgery and surgical anatomy, hygiene, jurisprudence, obstetrics, diseases of women and children, and the systematic lectures on medicine, surgery, and diseases of the eye and of the skin. The whole number of scholars is now 62, of whom 34 are male and 12 are female medical students, 14 are students of pharmacy, and 2 are the nucleus of a veterinary school.

The German Deaconesses' Hospital.

This is the best of the private hospitals in Cairo and admitted 457 patients during the year 1894. The admissions of the first and second classes have risen from 106 in 1893 to 168 in 1894, showing that the committee were quite justified in building new wards. Of the total admissions 100 were Egyptians, 72 were English and Maltese, and 69 were Greeks, the Germans themselves only contributing 46. The out-patient department was visited by 1033 patients for medical or surgical advice and by 23,058 for eye disease, and 698 operations were performed upon the eye patients. The infectious patients during the year were only 4—small-pox 2, diphtheria 1, and scarlet fever 1, and their nationalities were English, Swiss, and American. Of enteric fever there were as many as 31 patients, of whom 7 died.

Cairo, June 17th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Important Decision of the Supreme Court of the United State.

A WOMAN sued the Union Pacific Railroad Company for an injury to the spine, which she claimed had resulted from the fall of an upper berth of a sleeping car upon her. Three days before the trial the company asked the court for an order requiring the woman to submit to an examination by the company's physician, pledging to make it with as little exposure of the person as possible and in the presence of the medical man in attendance upon the woman. The court overruled the motion on the sole ground that it had not the right to enforce such an order. It was carried to the Supreme Court, which sustained the action of the lower one, saying that "such an examination is the invasion of the sanctity of the person to a degree that the law does not recognise, and that it is inconsistent with common law," and, further, the opinion said that "the court could not find that, until within a generation, it ever was thought that a court of common law had such a power as was claimed in this case." Justices Brewer and Brown dissented, and it is to be noted that they are the younger men on the supreme bench, who may be said to belong to, to understand, and sympathise with the generation now on the stage. Justice Brewer called attention to the "new times" in which we are living. He said that the actions for damages for personal injuries, now

Digitized by Google

so common, were very infrequent years ago, and that it was an open question and not determinable under the old common law procedure. If a person permitted exposure for the purposes of examination by the physicians who were to be called to testify in his or her behalf, it seemed to him but common justice that an order should be made for examination by the opposite side. He did not think it right that any person, where his or her interests were promoted after making disclosures of the person, should be allowed to refuse this permission to a physician representing the company sued on the plea of "sanctity of the person."

Suit against an Optician.

A public school teacher of New York sued a certain firm for $5000 because she had taken them a prescription for glasses, which they had filled, and the wearing of which was followed by severe vertigo—so severe, she claimed, as to lead to the loss of her situation as teacher. The mistake which the opticians made was to put the lens for the right eye in the frame for the left, and *vice versâ*. Expert testimony was called in and it was easily shown that an error had been made, but by no means $5000 worth of error, and the jury were undoubtedly influenced by the ulterior effect it had had in depriving the lady of her occupation. They awarded her $750, but the opticians appealed to the General Term, for they are resolved to establish a precedent; for if this precedent is to stand every optician will have to exact an agreement from his customer to be exempted from responsibility for his subsequent health. The glass accused of such deeply seated mischief was only two degrees stronger than the ordinary window glass, and was of the kind that women who want to be in the whole fashion cause to be put in a lorgnette when there is nothing the matter with their eyes. The plaintiff wore the glasses six months before she went to the opticians on account of her illness. Their lawyer said: "The opticians were no more responsible for what happened to her than a shoemaker would be if a man bought a pair of shoes and allowed the ones that belonged on the left foot to be put on the right foot, and after he had worn them in that way for six months, relying on the maker's reputation, should sue the shoemaker for damages because his feet were injured."

Dispensing with kissing the Bible.

Anyone who has acted as a witness in court and kissed the court Bible in taking the oath should understand the sanitary reasonableness of Pennsylvania's new law to dispense with the kissing. Nathaniel Hawthorne described the Bible he used in administering the oath to American waifs and strays who came to his Consulate in Great Britain as "greasy with perjuries."

Honouring the Discoverer of Ether.

There are fifty-three names of men, inscribed as a roll of honour, in the dome of the new House of Representatives in the State House at Boston. Each one is intended to mark an epoch or to commemorate a man who has beneficently influenced the course of events. Among them is that of Dr. William T. G. Morton, who was the man who instituted the series of experiments that established the use of sulphuric ether in the practice of medicine and surgery. His name deserves the honour given to it. The present contest for honours among the men who have made the antitoxin usable and useful sharply recalls the struggle, now nearly fifty years ago, for the honour of first using anæsthesia, and there were several first men, as is often the case. There was a claimant in Hartford who had used it in the painless extraction of a tooth, Morton in Boston, who really gave the ether for an operation by Dr. Bigelow, and Dr. Jackson, to whom many think the honour is due.

June 30th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

The Laying of the Foundation Stone of the Wanganui Hospital.

NOT, indeed, before it was needed was the foundation stone of the new Wanganui Hospital laid on March 14th last. This has been brought about through the generosity of the late Mr. Richard Reid, who lived for a long series of years in the Wanganui district, and who left the sum of £5000 to the Wanganui Hospital Board. It is curious to reflect that the late Mr. Reid occupied as his first billet in the colony the position of custodian to the hospital to which he ultimately bequeathed such a very substantial and munificent gift. This sum has been augmented by the New Zealand Government to the extent of £1500. Unfortunately, the gross total is not sufficient to meet the initial expenses of the first contract, but the Wanganui Hospital Board has very wisely—regarding the general condition of the existing hospital—considered itself warranted in undertaking a work which was so greatly needed, relying for the remainder of the necessary funds to complete the structure upon the generosity of the people and a further grant from the Government. The foundation stone was laid by the Hon. Richard Seddon, the Premier of New Zealand. The occasion was taken advantage of by the various friendly societies and the local Volunteers, who, mustering in full force, gave the proceedings an *éclat* which would have been otherwise wanting. The building, which will contain about twenty-five beds and all recent hospital improvements, will probably be completed about the end of the present year. It will be the first building of any magnitude built of brick on the west coast of the north island of New Zealand.

Antitoxin.

This remedy has at last reached the shores of the colony, and in the few cases in which it has been exhibited very satisfactory results seem to have been attained. The successful issue of the few cases treated here at the antipodes with the remedy will be hailed with satisfaction by the antitoxin enthusiasts in the mother country. It does not, however, seem very clear to medical practitioners in the colony as to the length of time after "manufacture" that the antitoxin serum holds its special virtue. Some of the tubes forwarded to the colony become "cloudy" in transit. "Does this cloudiness deprive it of its specific action?" is the question which has been asked. It has been well established that it is a very wise precaution on the part of medical men to look upon—and diagnose as such, for the matter of that—all cases of suspicious sore-throats of a membranous character as diphtheritic at the onset for the purpose of preventing the spread of the more serious malady; but all cases thus supposed to be diphtheritic are not truly so. Unless the cases be associated with nephritic changes, and perhaps followed by the development of peripheral neuritis, or the diagnosis has been made by bacteriological cultures, the certainty of the disease cannot be established notwithstanding the statement that diphtheria is said to be easily diagnosed. Busy medical practitioners have not the time (and very often not the means) to obtain bacteriological cultures, and to await developments would be suicidal when we have the antitoxin remedy at hand and we are still uncertain. It may, therefore, act as a charm in cases of follicular tonsillitis which are just on the mend, and we praise its special influence when we ought really to pat nature on the back. How diphtheria seems to take possession of some of the very healthiest country surroundings in this colony almost without a trace of its ingress is very difficult to conceive, but numerous instances of its appearance in this manner might be recorded. The honorary secretary of the Wellington Branch of the New Zealand Medical Association has forwarded a special letter of thanks to the New Zealand Government for its forethought in obtaining a supply of antitoxin. The honorary secretary, Dr. F. W. Mackenzie, states through his branch "that the remedy arrived just in time to meet a severe epidemic of diphtheria at the Upper Hutt and Petone, and has already been the means of saving several cases which would almost certainly have proved fatal without it."

Deaths under Chloroform.

Four cases of death under the influence of chloroform have occurred in this colony during the past few months, two of them having taken place in the dentist's chair. Operations about the mouth and pharynx have their own special dangers and difficulties, not only on account of the operative measures themselves, but also on account of the great care with which the anæsthetic requires to be given. It will, I feel sure, be soon established that it is safer policy to look upon all dental operations of any magnitude in the light of a serious matter and give the anæsthetic with all the surroundings of a surgical proceeding—viz., by carefully preparing the patient beforehand and doing the extraction the first thing in the morning in bed, at the patient's own house, if found possible. By following out this course in all instances much danger is eliminated.

Obituary.

THE RIGHT HON. THOMAS HENRY HUXLEY, P.C., F.R.C.S., M.D., F.R.S., LL.D., D.C.L., &c.

THE profession will have learned with deep regret of the death, on June 29th, of Thomas Henry Huxley, from complications following influenza, at Hodesles, Eastbourne, and will desire to express their sincere sympathy with his widow and family at their loss. With him a striking individuality has passed away and left the world distinctly the poorer. Besides contributing largely to the actual sum of knowledge that has accumulated during the past half century his clear and robust understanding exerted in this country, at a time when it was much needed, a very powerful, a very beneficial, and a very persistent influence on the pursuit and advance of science. Gifted with a quick and tenacious memory, possessing singular self-reliance, with the power of seeing at a glance into the very heart of things, abhorring shams, whilst thoroughly appreciative of sound knowledge derived from hard work and close observation, veracious and reliable in all that he said and did, though his sayings and doings often ran counter to established practice, he was one of the first to insist on the necessity for a material alteration in the method of education adopted in this country. And the modification he advocated with all the energy he possessed was the introduction of science into our schools and universities as a substitute for, or at least as holding equal rank with, purely linguistic or mathematical attainments so long held to be their chief or even exclusive function. That such scientific instruction should bear good fruit he maintained it should be taught objectively, through the senses of the learner and not by books, and he spared no pains to impress upon the public mind that it was the paramount duty of the Government, of wealthy individuals and rich companies, to found and endow research laboratories. The future predominance of the commercial power of England was, he maintained, essentially dependent upon whether her merchants had the wisdom to appreciate the gifts given to them by science, whilst the industries could only be properly developed by scientific methods and by a thoroughly scientific organisation. Earnest and painstaking to the last degree, he was himself a conspicuous example of the healthy and open mind that might result from this method of education; for, commencing life with fewer opportunities and poorer prospects than many of his associates, he raised himself by his indomitable energy and unwearied application to the foremost position amongst English men of science. The leading events of his life are given in the lively but unpretending autobiography prefixed to the recently published edition of his works. He was born on May 4th, 1825, at Ealing, his father being one of the masters in the large semi-public school of that place, then a village. He thought himself to be both in his physical and mental endowments the son of his mother, inheriting, however, an inborn faculty of drawing from his father. He notes it as a curious chance that his parents should have fixed for his usual denomination upon the name of that particular Apostle with whom he had always felt most sympathy. His school days were short, and he deliberately affirms that the society into which he fell during that period was the worst he had ever known. His great desire was to become a mechanical engineer, but the fates were opposed, and he commenced the study of medicine under a medical brother-in-law, becoming a student of Charing-cross Hospital in 1842. That part of the professional course which most interested him was physiology, because it deals with the mechanical engineering of living machines, and he felt through life a warm regard for Wharton Jones, who was then lecturer on physiology at the hospital, and from whom he received much kindly help, for his exact and extensive knowledge. When about fourteen years of age he attended a post-mortem examination, and in some unexplained manner, without cutting himself, was poisoned, became apathetic, and suffered from occasional paroxysms of internal pain, which he believed laid the foundation of his "constant friend, hypochondriacal dyspepsia." As a student he read discursively and unmethodically, but was able in 1845 to pass the First M.B of the London University, when he was placed second in honours, Dr. Ransom of Nottingham securing the first place. While still at the hospital he published his first paper, in which he described the layer of cells of the inner root sheath of the hair, which has ever since retained his name.

In 1846, having passed the examination of the Royal College of Surgeons of England, he applied to Sir William Burnett for a post in the medical service of the navy, and was speedily entered on the books of Nelson's old ship, the *Victory*, for duty at Haslar Hospital, where he was under the eye of Sir John Richardson, by whom he was appointed surgeon to H.M.S. *Rattlesnake*, commanded by Captain Owen Stanley, and bound for foreign service. The life on board ship in those days was not an easy one, but he justly remarks, "it was good for me to live under sharp discipline, to be down on the realities of existence by living on bare necessities, to find out how extremely well worth living life seemed to be when one woke up from a night's rest on a soft plank, with the sky for canopy, and cocoa and weevilly biscuit the sole prospect for breakfast, and more especially to learn to work for the sake of what I got for myself out of it." During the four years of absence he worked hard in the intervals of his duties and sent home his results to the Linnæan Society, by which they were ignored, and in 1849 forwarded one paper on the Oceanic Hydrozoa to the Royal Society, which was communicated by the Bishop of Norwich on June 21st, 1849. It constituted his first introduction to the scientific world. He declined an appointment to another ship and thenceforward devoted himself to natural history. That he applied for the chair of Natural History at Toronto and that Professor Tyndall was a candidate for that of Physics is well known. By their rejection of both candidates the Canadians lost and England gained two prizes. In 1851 he was elected a Fellow of the Royal Society, being then in his twenty-sixth year. In 1854 Sir Henry de la Beche, the Director-General of the Geological Survey, offered him the post, vacated by Edward Forbes, of Professor of Palæontology and Lecturer on Natural History at the School of Mines, which he held for many years. Here he delivered in 1863 to classes of working men his lectures on Man's Place in Nature, which led to an infinite amount of discussion and objurgation, and his lectures on Ethnology and on Our Knowledge of the Causes of the Phenomena of Organic Nature. In 1863 he was appointed Hunterian Professor at the Royal College of Surgeons of England, and held the post for more than five years. He twice filled the post of Fullerian Professor of Physiology at the Royal Institution. In 1869 and 1870 he was President of the Geological Society, and in the latter year President of the British Association for the Advancement of Science, when he delivered his celebrated address on Biogenesis and Abiogenesis. At this period of his life he was what other men would have called fully engaged with the duties of his office at the Geological Museum and School of Mines, and his work during the next ten years is to be found in the transactions of the various learned bodies of which he was a Fellow; but he found time to lecture or to write on the Physical Basis of Life, on Descartes, on the Automatism of Animals, on a Piece of Chalk, on Problems of the Deep Sea, on Some of the Results of the Expedition of H.M.S. *Challenger*, on Yeast, a Treatise on Comparative Anatomy, a Treatise on Physiography, another on Hume, an exhaustive article on Birds in the "Encyclopædia Britannica," and papers, essays, and reviews too numerous to specify, but which may be seen, or are referred to, in the pages of *Nature*. For some time he occupied a seat on the London School Board, but was compelled in 1871 to resign from failing health, after having untiringly urged the claims of science as one of the subjects to be taught. In December, 1872, he was elected Lord Rector of the University of Aberdeen.

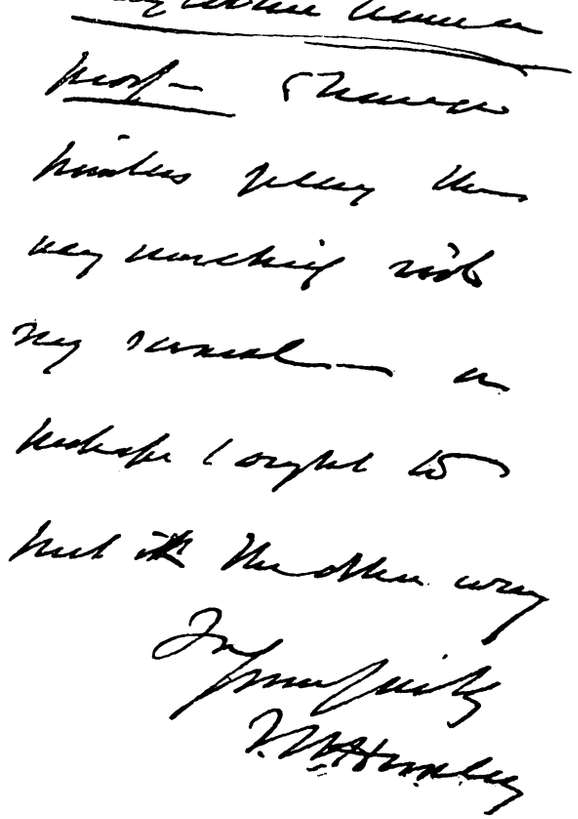
In 1883 he reached the culminating point of his career and was elected President of the Royal Society, giving in the same year the Rede Lecture at Cambridge. His incessant work in physics, chemistry, physiology, biology, and geology began now to tell upon his powers, and after serving on the Select Committee of the House of Commons on the Education, Science and Art Departments, and inaugurating the Marine Biological Institute, he was obliged to go abroad and shortly after to resign the Presidentship of the Royal Society. In 1892 he received in recognition of his high position in science and his services to the public the honourable distinction of being appointed one of Her Majesty's Privy Councillors. He had previously been honoured with the diplomas and doctorates of all the leading European Universities. The relations of Mr. Huxley with Darwin and with Darwin's hypothesis will probably hereafter be regarded as the central point on which all his work turned. Without his powerful aid, his valuable corroborative evidence, and his telling and

Digitized by Google

lucid exposition of the doctrines of Darwin, they would certainly have been far more slowly understood and accepted by those who had received no scientific training. The doctrine of the survival of the fittest had been advanced by Herbert Spencer. Mr. Huxley's own researches and observations were in the path simultaneously trodden by Wallace and Darwin. Evolution was in the air; but Darwin anticipated all his brethren by advancing the proposition that species originate by means of natural selection or through the preservation of the favoured races in the struggle for life. The value of this proposition, not as a proved theory, but as a working hypothesis explaining many facts that were previously unintelligible, was instantly perceived by Huxley, who was supported by the large experience of Hooker on the botanical side, and at first by Sir Charles Lyell on the geological, though the latter observer wavered at a later period. The conclusions which that hypothesis suggested, the gradual development of all plants and animals up to man himself from some low form or forms, the necessity for the lapse of enormous periods of time, and many other considerations gave a great shock to theologians; whilst it was rejected by naturalists of great eminence like Owen and Agassiz and was entirely ignored or ridiculed by the French *savants*. But the efforts of its champions in England, aided by the free thought of the Germans, won the battle; and few if any would be found to doubt the main doctrine of evolution now.

The originality of the opinions and doctrine he advocated, and the vigour with which he sustained them, were familiar to all who attended the meetings of societies in those days, and the bruit that there was likely to be a discussion in which Owen and Huxley were to take a part was sure to fill the room. As in so many similar cases, whether in speech or in essay, the older man, with assured position and accustomed to lead, seemed at first scarcely to recognise the force and acuteness of his adversary, and was inclined to look down as from a superior height "and smiling put the question by"; but this did not depress the younger combatant, and he returned to the charge again and again. Thus in the Proceedings of the Royal Society in 1854, Mr Huxley had stated that the intestine in terebratula ends blindly in the middle line or else terminates in a distinct anus between the pallial lobes. In the second edition of his work on "Invertebrata" (1855) Professor Owen, relying on the conditions present in orbicula and lingula as on his own dissections, commented on this statement and remarked, "There may be blindness somewhere, but not, I think, at the termination of the intestine of terebratula." In his lectures on the Elements of Comparative Anatomy (1864) Mr. Huxley vindicated his accuracy by quietly observing that his statements had been fully borne out by Mr. Albany Hancock and by M. Lacaze Duthiers, two of the best minute anatomists of the day. I trust, he adds, Mr. Owen is now fully satisfied as to where the "blindness" really was in 1855. It is delightful to find after these passages-of-arms that Huxley, in his charming obituary notice of Owen in the Proceedings of the Royal Society, wrote no line that betrayed remembrance of any bitterness, but, on the contrary, bestowed all due and kind recognition of the great qualities and influence on the age of the great anatomist with whom he had so often fought.

It is not surprising that amongst the many subjects upon which he concentrated the "dry light" of his understanding theology should constitute one—perhaps, as Herbert Spencer always maintained, from inborn clerical proclivities; perhaps from irritation arising, as he once said, from the "cackle of curates in the nearest cathedral town"; and perhaps from a still deeper feeling—the discovery of truth. He pursued doctrinal theology with ardour, attempting to apply the methods of science to the Old and New Testaments alike, and judging that by reason which can only be comprehended by faith. In the late Bishop of Peterborough, Principal Wace, and Mr. Gladstone he had three formidable antagonists; but no whit dismayed he returned blow for blow, and the discussion of the story of the Gadarene pigs amused, though it scarcely edified, the ordinary reader of magazine articles. From an early date there was, he found, so much that was inexplicable and unintelligible that he coined the phrase agnosticism, and avowed himself an agnostic, terms that, although they were inoffensive enough in themselves, were confused by laity and clergy alike with atheism, and gave rise to long and bitter controversy.



The term "agnostic," he avowed, came into his head as suggestively antithetic to the Gnostic of Church history who professed to know so much about the very things of which he was ignorant, and he took the earliest opportunity of daring it at the Metaphysical Society to show that he, too, had a tail like the other foxes, and to his great satisfaction the term took with the public.

His voice was not infrequently heard upon the social questions of the day, and he spoke with no uncertain sound, but not carelessly or without due inquiry into the merits of each case, as one or two examples which will occur to our readers at once sufficiently testify.

In person he was of moderate height, strongly but rather slenderly built, with a long head. His complexion and hair were dark, his face without a ray of colour in it. His eyes were very dark, with keen and lively expression; his jaw square, with mobile mouth and a deep dimple below the lower lip; the nose a little *retroussé;* his voice was musical; his movements were quick; his address pleasant and quiet. He tells us his mother used to say, looking at him almost reproachfully, "Ah! you *were* such a pretty boy," whence he had no difficulty in concluding that he had not fulfilled his early promise in the matter of looks.

It remains only to add that Professor Huxley occupied many positions and shone in them all. As a man of science he was at once accurate, profound, and versatile. As a speaker, lecturer, and teacher he was clear, fluent, and racy; his illustrations, drawn now from Greek or Roman history, now from the "Arabian Nights," from "Robinson Crusoe," or some nursery tale, were always apposite and amusing. As a writer his style was pellucid and forcible. As a debater and controversialist he was ready and good tempered, pugnacious but rarely vituperative—a terrible opponent, as many found who crossed swords with him. Perfectly fearless, with a singular faculty of discovering the weak point of an argument, he cared not with whom he engaged. Like Launcelot of old—"king, duke, earl, count, baron—whom he smote he overthrew." As a friend he was reliable and constant; in all the common relations of life, courteous, affable, cheerful and unpresuming. He was truly a king amongst men. His like will not soon be seen again.

We have pleasure in presenting to our readers a facsimile of part of a letter (dated Nov. 21st, 1893) from Professor Huxley, which includes his signature. It will be noted that with characteristic thoughtfulness he refrains from throwing all the blame for "the very mischief" of bad "proofs" upon the printers.

WILLIAM LEIGH, M.R.C.S. ENG., L.R.C.P. LOND.

THE sudden death of Mr. William Leigh of Chiswick, which occurred on Tuesday, June 25th, will be unexpected and sad news to a large number of his friends at Chiswick and in the profession. Mr. Leigh was educated at Epsom College and St. George's Hospital, taking the diplomas of the Royal College of Physicians of London and the Royal College of Surgeons of England in 1865. The succeeding five years he spent in the office of house surgeon and surgical registrar and chloroformist at the hospital, where he was well known and much liked. At the conclusion of his curriculum he joined his father, who had been practising nearly forty years, and continued the practice after his death about ten years later, when he succeeded to the surgeoncy of the Chiswick and Turnham-green Dispensary. William Leigh, in his education and traditions, was a thorough representative of the old-fashioned family practitioner. He possessed a sound practical knowledge of the several branches of his profession, gathered from close observation and contact with his teachers and cases in the hospital wards, and in practice, rather than from lectures and reading. A man of quiet and methodical habits, he was perhaps little known outside the sphere of his own immediate activity; but those who were brought in contact with him recognised his sterling qualities and liked him much. His wonderful uniformity of manner and undeviating regularity of conduct, with the self-confidence born of his thorough familiarity with his work, made him welcomed and trusted by his patients; but to the few who really knew him intimately his unhesitating self-sacrifice and steady devotion inspired such love and confidence as make the loss irreparable. But though his sudden decease came with such sorrow to his friends, to himself the end was apparently without suffering. He had left home for a few weeks to recruit after the strain of the early part of the year, and was enjoying the change up to the last minute, when he stepped on board a steamer to cross from Glasgow to Ireland, and with scarcely a moment's warning fell into a chair and expired in the presence of a brother practitioner, Dr. Speer of Belfast. The deceased was fifty-two years of age. At an inquest held on June 27th by Dr. J. Adams, coroner for Mid-Antrim, the jury returned a verdict of "Death from apoplexy," in accordance with Dr. Speer's evidence.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF COUNCIL.

THE seventh election of Fellows to fill the vacancies on the Council of the College under the new regulations was held in the library of the Royal College of Surgeons, Lincoln's Inn-fields, on Thursday, the 4th inst., between 2 P.M. and 4 P.M. The result of the voting was as follows:—

	Votes.	Plumpers.
MR. ALFRED WILLETT ...	... 415	1
MR. FREDERICK TREVES	... 326	5
MR. H. T. BUTLIN ...	... 323	2
MR. ALFRED COOPER ...	... 295	20
DR. J. WARD COUSINS ...	... 284	4
MR. J. N. C. DAVIES-COLLEY	... 249	30
MR. A. T. NORTON ...	... 247	4
MR. H. W. PAGE	... 237	7
MR. WILLIAM ANDERSON ...	... 210	18

Mr. Willett was declared to be re-elected a member, and Messrs. Treves, Butlin, Cooper, and Cousins were elected members. There were 621 voting papers received.

This is by far the heaviest poll that has ever been taken in the election of Members to the Council, a result to be attributed to the facilities offered for voting by the post.

We shall report the meeting of Fellows next week.

THE Secretary of the Royal British Nurses' Association asks us to state that it is impossible that the agenda for the annual meeting should appear in this week's number of THE LANCET, but that they will be ready for publication next week.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on Monday, July 1st:—

Anatomy and Physiology.—Henry James Taylor and William Atkin Thompson, Owens College, Manchester; Herbert Sherwell Clogg, University College, Cardiff; Thomas Wafer Byrne and Michael Robert Maher, University College, Liverpool; Arthur William Statter Curtis, Oswald Herbert Rogerson, William Hearfield Galloway, Percy Ellwant Middleton, Richard Milnthorp, and Ernest Arnold Wraith, Yorkshire College, Leeds; James Phillips, Edward Mountjoy Pearse, and Franklin Cox, University College, Bristol; Irwin Browne Richardson, John Austin O'Dowd, William Alfred Henshaw, John Owen Harvey, and Richard Charles Baker Hall, Mason College, Birmingham; and Edgar Robert St. John Cars, Michigan University, U.S.A.

Anatomy only.—Charles Henry Bradbury, Owens College, Manchester, and Stanley Wellby, Oxford University and St. Thomas's Hospital.

Physiology only.—George Whittenbury White, Firth College, Sheffield; Stuart Bathgate Reid, Cambridge University; Charles Martin Mitchell and Frederick Charles Morgan, University College, Bristol; and Lionel Hugh Lewis, Guy's Hospital and University College, Cardiff.

Sixteen gentlemen were referred in both subjects, four in Anatomy only and one in Physiology only.

Tuesday, July 2nd:—

Anatomy and Physiology.—Sydney Henning Belfage and Charles Hugh Bidwell, University College, London; Alfred Gentel and Charles Dominic Leyden, St. Mary's Hospital; James Cowan, Queen's College, Belfast; Percy Dodd Pywell, St. Thomas's Hospital; Herbert Cecil Barlow, Westminster Hospital; William Ernest Amsden Worley and Egbert Coleby Morland, St. Bartholomew's Hospital; Donald Kilve Luttrell Nasmyth, Charing-cross Hospital; and John Penn Milton, King's College, London.

Anatomy only.—Robert Stanley Ransome, George Herbert Dominy, and Arthur Ernest Malaher, St. Thomas's Hospital; Owen Tredwell Atherley Phillips, University College, Cardiff; and Nicolas Buendia, St. Bartholomew's Hospital.

Physiology only.—Ernest John Distin, King's College, London; Thomas Hill Bailey, King's College, London, and Mr. Cooke's School of Anatomy and Physiology; Arthur Wellesley Penrose, Edgar Ashby, and Joseph Lewin Payne, Guy's Hospital; Walter Green and William Hodgson Park, Charing-cross Hospital; Albert John Pattison, London Hospital; John Maclean Carvell, London Hospital and Mr. Cooke's School of Anatomy and Physiology; George Beley, St. Thomas's Hospital; and Francis Augustus Pitts-Tucker, St. Thomas's Hospital and Mr. Cooke's School of Anatomy and Physiology.

Eleven gentlemen were referred in both subjects, eight in Anatomy only, and three in Physiology only.

Wednesday, July 3rd:—

Anatomy and Physiology.—Charles Gordon Watson, Arthur Oliver Bird Wroughton, and Ronald Hatfield, St. Bartholomew's Hospital; Cecil Maurice Goodbody, Ernest Frederick Charles Dowding, Bernard Featherstone Howlett, and Allan Gordon Graham, St. Thomas's Hospital; Thomas Leah, David Bellios, William Henry Singer Liddell, and John Henry Lightfoot, St. Mary's Hospital; Leonard Dimock Saunders, King's College, London; Horace John Maurice Drummond Sale Barker and Cyril Shepherd, Guy's Hospital; William St. Aubyn Fortescue Hubbard, Charing-cross Hospital; Henry Thompson Barrow, Westminster Hospital; Frank Mayo Morris, Herbert George Frankling, and James Alfred Patrick Cullen, London Hospital; and Christian Beverley Fairbank, University College, London.

Eighteen gentlemen were referred in both subjects.

THE VICTORIA HOSPITAL FOR CHILDREN.—Their Royal Highnesses the Duke and Duchess of York received a deputation on Monday morning at York House from the Victoria Hospital for Children. In the absence of the Right Honourable the Earl Cadogan, K.G., President, who was unavoidably prevented from attending by press of business in connexion with his appointment as Lord Lieutenant of Ireland, Mr. Martin R. Smith, Chairman, and Captain Blount, R.N., Secretary of the Hospital (at whose suggestion the Infant Prince Fund had been formed), presented to their Royal Highnesses, printed on a white satin roll inclosed in a dark-blue morocco case, the names of all the contributors to the "Infant Prince Fund," which fund had been inaugurated in commemoration of the birth of the Prince, as the fourth heir in direct succession to the throne. With the sum contributed—about £1400—a cot has been endowed in perpetuity in the Victoria Hospital for the use of the sick and suffering children of the poor and presented to His Royal Highness Prince Edward of York, on the first anniversary of his birth. Their Royal Highnesses, in accepting the gift on behalf of the young Prince, expressed their great satisfaction with the amount that had been so generously subscribed, and hoped that when old enough the Prince would fully appreciate the kindly feeling which had prompted this benefaction.

LITERARY INTELLIGENCE. — Messrs. William Wood and Company, Medical Publishers of New York, have appointed Mr. Edward Arnold, 37, Bedford-street, Strand, London, sole agent for the sale of editions of their books in the United Kingdom.

A BAZAAR in aid of the funds of St. Mary's Hospital was opened by H.R.H. the Princess of Wales on June 27th at the Portman-rooms, Baker-street. Sir William Broadbent, senior physician to the hospital, received the Royal party, and after the usual ceremonies presented to the Princess Lady Broadbent, Colonel Stanley Bird, the Rev. C. J. Ridgway (chairman of the bazaar committee), Mr. Malcolm Morris, and Mr. Field, the Dean of the Medical School. A large stock of ornamental and fancy articles were offered for sale at the stalls, of which there were twenty, the most showy being the one conducted by Mrs. Field and Mrs. Anderson Critchett. The bazaar remained open for three days, and its attractions were enhanced by music, recitations, and dramatic sketches.

THE DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on June 26th, Dr. Pye-Smith, F.R.S., President, being in the chair.—Dr. Shephard Taylor showed a Hypertrophied Nail which had been removed by Dr. Collier of Yarmouth from a woman's thumb. It was about three inches in length and nearly straight; it had been growing for eleven years, and had originated after an accident.—Dr. Eddowes showed a woman with considerable Hypertrophy of the Nails of both Great Toes; they were curved like a ram's horn, and had not been cut for the last twenty-five years.—Dr. Stowers showed a young woman suffering from an Affection of the Nails, the matrix having receded from the nail, which, as it grew, became curved and brittle, similar to the condition seen in eczema and psoriasis, although there was no evidence of either disease in this case. The following cases were also exhibited:—By Dr. Eddowes, Angiokeratosis of the Right Leg; by Mr. Bidwell, a Rodent Ulcer of the Thigh; and by Dr. Abraham, a case of Bromide Rash in a woman aged twenty-six years who had been taking bromide on and off for thirteen years.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Friendly Societies Bill.

THIS Bill, which incorporates a number of the recommendations of the Royal Commission on the Provision for the Aged Poor, has been passed through both Houses of Parliament as an unopposed measure.

Food and Drugs Adulteration.

The Select Committee of the House of Commons on this subject, which has been taking evidence during last session of Parliament and this, held a meeting on Tuesday, July 2nd, when it was determined to report the evidence taken to the House, and suggest that the inquiry should be proceeded with in another session.

Factories and Workshops Bill.

The Grand Committee on Trade at its meeting on Monday, July 1st, completed the consideration of the Factories and Workshops Bill. At its previous meeting it dealt with a number of interesting points. For instance, it determined, on the suggestion of Mr. Asquith, to insert a proviso prohibiting for the future the use of underground bakeries unless they have been used as such before the passing of the Act. Mr. Asquith assured the Committee that this proviso will not interfere with trade, and intimated that in its favour there was a consensus of opinion among both masters and workmen. Mr. John Burns put forward the suggestion that in order to meet the case of existing underground bakehouses the Home Secretary should fix a date beyond which they should not be allowed to continue. Clause 25 of the Bill prohibited the use of lead or arsenic in any factory or workshop in the process of tinning or enamelling metal hollow-ware cooking utensils, but Mr. Asquith said he did not attach much importance to the clause, and the Committee decided to strike it out. At the final meeting, on Monday, July 1st, a considerable amount of time was spent over Clause 30, which in its original form provided that in every factory and workshop in which the business of making wearing apparel was carried on the temperature should be kept up to not less than 60° F. Mr. Hayes Fisher, acting on behalf of Mr. Bousfield, moved to extend the provision to all factories and workshops. Mr. Asquith said that the clause had been confined to places where wearing apparel was made—first, because it was in respect of those places that by far the larger number of complaints was made; and, secondly, because it was thought it would not be possible to apply the same figure to every factory. On further consideration, however, he had come to the conclusion that it would be desirable not to insert a fixed and invariable minimum temperature, and he was prepared to accept the proposed extension, as well as an amendment standing in the name of Mr. Gerald Balfour to insert the words "adequate measures shall be taken for securing and maintaining a reasonable temperature." The Committee agreed to this course, so the provision was made for "a reasonable temperature" in all factories and workshops. Sir Charles Dilke suggested the introduction of words with regard to ventilation, but it was felt by the Committee that in view of the provisions of the principal Act they were unnecessary. When the clauses in the Bill had all been gone through, Mr. Asquith made an appeal to members who had given notice of new clauses not to move them, but to allow the Bill to be regarded as complete in the meantime. This appeal had special reference to a number of new clauses dealing with half-timers, which were certain to have raised many points of controversy and occupied a considerable amount of time. Yielding to Mr. Asquith, the members concerned withdrew their proposals, with the result that at the close of the sitting the Chairman of the Committee found himself in a position to report the Bill to the House.

Hospitals and Sanitation in India.

A Parliamentary paper has been issued giving a statement with regard to the moral and material progress and condition of India during the year 1893–94, a large portion of which is devoted to the subjects of hospitals and sanitation. It says, *inter alia*, that the number of hospitals and dispensaries has increased from 1411 in 1886 to 2018 in 1893, that the number of in-patients treated has increased from 243,000 to 327,000, and that the total of in-patients and out-patients has increased from 10,309,000 to 17,075,000. The number of successful vaccinations has increased from 4,951,000 in 1886 to 6,716,000 in 1893; of this latter number two and a half millions were infants under one year, and three millions more were children between the ages of one and six years. Later there occurs the following passage: "Fevers are the great scourge of Indian populations; against fever quinine is the best known remedy; cinchona gardens have for years been established on the Sikkim and the Nilgiri Hills; quinine is made now at both these places by a new and simple process; supplies of the medicine are sent thence to hospitals and sold to the public; and during the last few years thousands of pounds of quinine have been made up into three-grain packets for sale to the public at local post-offices at a cost of one pice (less than a farthing) per packet. In 1893-94 between three and four millions of these packets were sold in Bengal alone." On the subject of sanitation, the report says that the work of procuring the regular registration of deaths and births has been diligently prosecuted throughout British India. Computations based on the census results of 1881 and 1891 have been held to justify an estimate that the average birth-rate of all India over a series of years is about 48 per 1000, and the average death-rate is about 39 per 1000. Among the native populations the great majority of deaths are ascribed to fever in all years, but the death-rate from zymotic diseases shows great variation, due apparently in great measure to climate. The reported cholera deaths for British India were 269,852 in 1888, 417,017 in 1889, 291,202 in 1890, 582,430 in 1891, 724,015 in 1892, and 216,827 in 1893. Much attention, it is added, has been given to improving the sanitary condition of pilgrims and of the crowds at great places of religious resort.

Inquiry as to Cause of Death.

On the motion of Sir Seymour King, the House of Commons agreed, on Tuesday, July 2nd, to present an address to Her Majesty for a "return of the report of an inquiry, ordered by the Secretary of State for the Home Department, into the causes of the death of a patient named Thomas Weir at St. Ann's Heath, Virginia Water, held by Mr. Gully, Q.C., assisted by Dr. George H. Savage."

Distress for Want of Employment.

The Select Committee on this subject has stopped its inquiry and presented a short report, containing one or two suggestions of minor importance and recommending the appointment of a committee in the new Parliament to complete the inquiry. The evidence already taken will be published as a Parliamentary paper.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

THURSDAY.—BRITISH GYNÆCOLOGICAL SOCIETY.—Specimens by Dr. Purcell and Dr. Bantock. Adjourned Discussion on Dr. Fancourt Barnes's paper on "Some Difficulties in the Use of the Curette." Dr. Halliday Croom: A case of Glycosuria complicating a large Ovarian Cyst. Dr. Sambon of Rome will exhibit and explain some Roman Antiquities relating to Obstetrics and Gynæcology, mostly votive offerings dug up in Italy.

NEUROLOGICAL SOCIETY OF LONDON (National Hospital for Paralysis, Queen-square).—8.30 P.M. Dr. Risien Russell: Congenital Defect of the Cerebellum in a Puppy.—Dr. Colman: Disease or Defect of the Cerebellum in a Cat.—Dr. Alex. Bruce: (1) Acute Neuritis in Optic and Posterior Tibial Nerves, and Peculiar Degenerative Changes of Muscle; (2) Syringomyelia; (3) Double Facial and Double Auditory Paralysis from Syphilis of the basal Dura Mater and Bones.—Dr. Macintosh and Dr. Aldren Turner: (1) Exhibition of Tumours involving the Capsulo-thalamic Region; (2) Two cases of Syringomyelia; (3) A Rare Form of Infiltrating Glioma of the Spinal Cord.—Dr. G. Newton Pitt: Two Spinal Cords with Posterior Sclerosis associated with Profound Anæmia.—Dr. Hubert Bristowe: New Growth of Lumbar Cord.—Dr. F. W. Mott: Preliminary Note on the Chemistry of Degeneration of the Central Nervous System. Dr. Prandi (of Buda Pesth) will exhibit Specimens illustrating some cases of Alteration of the Posterior Columns in Pseudo Tabes, Arterio-Sclerosis, Diabetes, and Senile Alterations.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—6 to 6 P.M. Dr. Morgan Dockrell: Syphilis.

SATURDAY.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Pityriasis Rubra Pilaris.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the current half-year was given in last week's issue, which completed the first volume of the year 1895. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1895 are now ready. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s*.

To be obtained on application to the Manager, accompanied by remittance.

THE LANCET AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

FEES FOR CONFINEMENTS.

To the Editors of THE LANCET.

SIRS,—Will you kindly give your opinion as to what amount of attendance following a confinement is covered by the ordinary fee? In the particular case which I have in mind the confinement fee was paid within a day or two of delivery. Subsequently some fifteen or sixteen visits were necessary, owing not to any special complications, but to the general tardiness of recovery and to the prematurity of the child. In addition to this an attack of acute mastitis occurring in the fourth week necessitated two or three more visits. Your advice in such cases will be much appreciated.

I am, Sirs, yours faithfully,

June 29th, 1895. A SUBSCRIBER.

*** Something depends on the means of the patient. If these are good any attendance after the ninth day might reasonably be charged r.—ED. L.

THE LIABILITY OF FRIENDLY SOCIETIES FOR NEGLIGENCE OF THEIR MEDICAL OFFICER.

THIS question was raised in an action lately brought by Richard Barnes, a clerk, against the Lincoln Oddfellows Medical Association to recover damages in respect of a case of miscarriage in his wife attended by the medical officer of the Association. Certain very important points of law touching the liability of such societies for the negligence of their medical officers were reserved, on which judgment has just been delivered at the Lincoln County Court by his Honour Judge Shortt. The following is the report of the *Yorkshire Post* on these points. It would be well if the appeal granted by the judge were acted on, as they are of great interest both to friendly societies and the medical profession.

"On the points of law involved plaintiff contended that the defendants were liable on one, if not both, of two grounds—(1) by reason of their breach of contract to supply efficient medical attendance in accordance with the rules; (2) on the ordinary ground of the liability of a master for the negligent act of his servant. For the defendants it was replied—(1) that the contract to supply efficient medical attendance was fulfilled by securing for the members a fully qualified medical attendant; and (2) that they were not liable on the second ground, because the relation of master and servant could not be held to exist between the society and its medical officer, as that relation exists only in cases where the employer can not only order that a certain thing should be done, but can also direct and control the manner in which it is to be done. It was contended (thirdly) on behalf of the defendants that as to midwifery cases there was no contract with the society, nor did the society assume any obligation or interfere in such cases at all. His Honour held that the defendants could not be held liable either in contract or *in tort*. He considered that their general contract to provide efficient medical attendance was fulfilled by securing to the members the services of a fully-qualified medical attendant. It was admitted by counsel for the plaintiff that the defendants could not be charged with negligence in their appointment of him or in continuing to retain him. His Honour did not think it necessary to decide the abstract point (hitherto undecided in this country) whether the relation of master and servant could be said to exist in such a case as the present; for he was of opinion that, in dealing with midwifery cases at any rate, the medical officer could not be regarded as the servant of the society, as they could not order him to treat at all. That this particular case was a "midwifery" case was found by the jury—so far as the question was one of fact. So far as it was one of law he answered it in the same way. On this ground he held that the defendants were not liable, and that the plaintiff's remedy was against the doctor alone. If leave to appeal were necessary he should grant it willingly, as the points of law involved were of some nicety and difficulty. Judgment for the defendants, but without costs."

Greenhorn.—We do not know of any reliable book giving the exact information sought. In one or two such books the descriptions of symptoms are decidedly incorrect, and calculated to raise unnecessary alarm. In no very long time the services of a medical man will be required. Why not see the selected practitioner and state the difficulty now?

Mr. R. J. Wylie should consult a reliable advertising agent.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—On March 15th A and B met in consultation. On July 17th B is called by the patient to attend him. Prior to seeing the patient B inquires from patient's friends if A is aware that B is to be called in. They reply "that a letter on the subject has been written and forwarded to A." The case is of a chronic nature. B calls on A the same evening and reports what has taken place, A at that time making no objection whatever. Has B in any way acted unprofessionally?

I am, Sirs, yours faithfully,

New Zealand. ORNITHORHYNCHUS.

*** B's conduct appears to us irreproachable. He inquired if A had been made aware of the intention to call him in and he called on A after the visit. We cannot see, from the facts laid before us, what more could be expected from him, or what more he could do.—ED. L.

WANTED, A HOME FOR AN INEBRIATE.

To the Editors of THE LANCET.

SIRS,—A gentleman who has lately become an inebriate wants to enter a home for inebriates. He is eighty years of age and has an income of £60 a year. Will any of your readers kindly suggest such a place which would be suited to his limited income?

I am, Sirs, yours faithfully,

June 30th, 1895. R. E. P. S.

"HOUSE SURGEONS AND CORONERS' INQUESTS."

To the Editors of THE LANCET.

SIRS,—May I be allowed, in reference to your recent annotation under this title, to call attention to what I consider is another hardship that we house surgeons have to bear in reference to coroners' inquests? We are called to give evidence at every inquest that is held on patients dying in hospital, no matter what is the cause of death, however evident it may be. Now, had many of these occurred outside, the medical man in attendance would not be called just because he would have to be paid, but we, poor wretches, who have to give evidence for nothing, always have to appear. Now, if the coroner calls us, it must be because he considers that our evidence is necessary; that being so, why does he not call the general practitioners in similar cases? The case I have particularly in view was one in which a child was severely burnt and died in two days, and yet the medical man who attended was not called at the inquest. We are always called in these cases.

I am, Sirs, yours truly,

June 23rd, 1895. H. S.

Gratis.—The case is peculiar. It seems to us that our correspondent's first step should be to complain to B. of the arrangement by which he sees the patients of other medical men. The fact that our correspondent is not on friendly terms with A. and B. does not affect his right or his duty to protest against such a system. We cannot say that B. is acting unprofessionally so long as no objection is made; but we should think otherwise if he disregarded a respectful protest from a neighbouring practitioner, whose patients he attended at the call of a midwife. Neither can we recommend our correspondent to attend cases for nothing by way of checkmating the objectionable arrangement described. The first thing to be done is to point out to his neighbour that he is, perhaps unwittingly, seeing the patients of other medical men.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—One statement made by Mr. Feeny in your last issue is not correct. In Germany, Switzerland, &c. every medical man who wishes to practise has to pass the State examination. This gives him the title of Arzt (Médecin), and the right to practise as such; but no one is allowed to call himself a doctor until he has passed the M.D. examination of a university, which is a different thing altogether. Whether the M.D. is a German, Swiss, or a foreign one matters little; because the M.D. alone does not give the right to practise, and all medical men, with very few exceptions, pass both examinations. If anyone abroad dared to propose, like Mr. Feeny, that the State examination should give to a man the right to call himself a doctor he would undoubtedly be lynched by the Rector Magnificus and the whole professorial staff of the nearest university. I am, Sirs, yours obediently,

Harley-street, W., July 2nd, 1895. J. KESER.

To the Editors of THE LANCET.

SIRS,—I must protest against the statement which appears in a letter signed "Not L.S.A." in your issue of the 29th ult.—that "the L.S.A. is by right entitled to call himself 'Dr.'" An L.S.A. is an apothecary, and nothing more, and has no more right to call himself "Dr." than a curate has to call himself "Archbishop of Canterbury." If the licence of the Society of Apothecaries gives its holder a kind of legal right to act as a general practitioner it gives its holder no right to assume distinctions that a *college* or a *university* alone can give. It is quite time that the Society of Apothecaries of London and the Apothecaries Hall of Dublin ceased to grant their licences, which are not now wanted, the pharmaceutical societies having supplied the want.

I am, Sirs, yours faithfully,

Erdington, July 2nd, 1895. WILLIAM DONOVAN, M.D.

To the Editors of THE LANCET.

SIRS,—Your correspondent "Not L.S.A." repeats a statement which has on two or three occasions been recently made—viz., that "the L.S.A. is by right entitled to style himself 'Dr.'" It would be interesting to know on what basis this assertion rests. I know that some of the dictionaries give the meaning of "doctor" as "a physician, an apothecary, one who has taken the highest degree in the faculties of divinity, law, physic, or music," but I should like to know what "right" the L.S.A. has to the title which is not equally that of any other licentiate in medicine. Perhaps "Not L.S.A." will explain.

I am, Sirs, yours truly,

July 2nd, 1895. A. Z.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of the 29th ult. "Not L.S.A." writes that "the L.S.A. is by right entitled to style himself 'Dr.'" May I ask him kindly to give his authority for the statement, as it does not appear to be generally known? I am, Sirs, yours faithfully,

July 1st, 1895. E. F.

THE SMALLWOOD HOSPITAL, REDDITCH.

Dr. Herbert Page.—The rule is open to the objection made by our correspondent; but it will not necessarily be abused, and there will be no harm in assuming till the contrary appears that the house committee will use it with due respect to the medical attendants of patients admitted and to their own staff.

S. A. H. T.—Our correspondent is advised to apply to "The Secretary, College of Preceptors, Bloomsbury-square, W.C." Much information of interest to medical students will be found in the Students' Number of THE LANCET, Sept. 1st, 1894, and in the number which we shall publish on Sept. 7th of the present year.

"A BOOK ON TOBACCO."

To the Editors of THE LANCET.

SIRS,—In reference to a query as to a book on tobacco I would recommend Mr. Ludwig Kohn to consult an article on smoking which appears in a work published many years ago on "Diseases of Modern Life," by Dr. Benjamin Ward Richardson.

I am, Sirs, yours truly,

July 1st, 1895. S. WESLEY WILSON.

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Ludwig Kohn, in your issue of June 29th, will you allow me to inform him and others that a book upon the above subject, entitled "The Use of Tobacco condemned by Physicians, Experience, Common Sense, and the Bible"; also tracts, pamphlets, &c. may be obtained from this office? The price of the above book is 2*s.* 3*d.* cloth and 1*s.* 2*d.* paper covers.

I remain, Sirs, yours respectfully,

Manchester, July 1st, 1895. JAMES B. DAVIS.

*** Mr. Davis is secretary of the English Anti-Tobacco Society (Offices: 25, Market-street, Manchester), so that it is fair to suppose that the properties of tobacco are discussed from an antagonistic standpoint.—ED. L.

W. H. S.—Our correspondent cannot have told us all, though he may have told us all that he knows. From his account the conduct of a fellow practitioner would be "without known parallel," but the second opinion must have been sought by somebody. It could not have been given in the manner described *against* the wishes of the patient and her husband. We can express no opinion on the matter from the information supplied to us.

A QUESTION OF RESPONSIBILITY.

To the Editors of THE LANCET.

SIRS,—Kindly give your opinion on the following. A is paid a fixed yearly sum to attend accidents at D's factory. An accident takes place during A's absence and the patient is brought to B. B does everything necessary and tells patient to see A. A says he cannot remunerate B for his services. D considers himself relieved by salary he gives A. Who is responsible for B's fee?—I am, Sirs, yours truly,

July 1st, 1895. PERPLEXED.

*** If A did not actually delegate B to do a portion of his work for him, it would seem that A has incurred no legal responsibility. On the other hand, D's attitude is very comprehensible. Yet B must be paid. The responsibility will, we think, depend upon the circumstances of the case under which B's services were invited. Who sent for him, and how urgent was the case?—ED. L.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Leicester Post, Sussex Daily News, Glasgow Evening Mail, Morning Leader, Liverpool Courier, Weekly Budget, North British Daily Mail, Science Siftings, Manchester Guardian, Scotsman, Gray's Standard, Brisbane Courier, Cheltenham Free Press, Yorkshire Herald, Bradford Observer, Remarks, West London Observer, Irish Times, Newcastle Chronicle, Wolverhampton Chronicle, Cork Constitution, Truth, Public Opinion, Family Doctor, Times of India, Pioneer Mail, Architect, Sanitary Record, City Press, Builder, Brighton Gazette, Kensington News, Liverpool Daily Post, Bristol Mercury, Madagascar News, West Middlesex Standard, Yorkshire Post, Hertfordshire Mercury, Leeds Mercury, Weekly Free Press and Aberdeen Herald, Mining Journal, Reading Mercury, Weekly Times and Echo, Surrey Advertiser, Spalding Free Press, Local Government Journal, Temperance Chronicle, English Mechanic, London, Manchester Courier, Nottingham Daily Express, Tottenham Standard, Coventry Herald, Australian Medical Journal, Public Health, Evening Telegraph (Dundee), Cheltenham Mercury, Goole Times, Brighton Guardian, &c., &c.*

The Cavendish Lecture
ON
DREAMY MENTAL STATES.

Delivered before the West London Medico-Chirurgical Society on June 20th, 1895,

BY SIR JAMES CRICHTON-BROWNE, M.D., LL.D., F.R.S.,
LORD CHANCELLOR'S VISITOR.

(*Continued from page 5.*)

WE have all heard of these strange sensations and impulses, psychical reflexes, which have led to suicide by precipitation under such circumstances, and of the fascination which has caused bystanders to yearn to throw themselves in front of a swiftly passing train, and we may perhaps discover in these phenomena analogues of dreamy mental states. A friend of Arthur Hugh Clough once told me that on one occasion on which the poet was visiting him in Wales he took him for a walk and conducted him to a grassy slope terminating in a wall which formed the parapet of a huge cliff, with a sheer descent of three or four hundred feet. The wall, a rough stone one, looked simply the boundary of a field, and no one approaching it on the landward side could have any conception of what lay beyond it. The poet, being brought up to the wall, was asked to look over it, and on doing so had suddenly disclosed to him the beetling promontory, the wrinkled ocean beneath, and the circling flakes of white sea birds between, and with a very startling effect. He fell back on the grass pale and shivering, and exclaimed, "Oh, my God! what a fearful sight!" and then turned and said to his friend, "My life seems shrivelled up before me. For Heaven's sake give me some brandy!" But there was no brandy to be had, for the nearest house was four miles off, so nothing could be done for him in his distress but to sprinkle his face with water. He lay on the grass for half an hour ghastly and sick, like a man at the point of death, and it was then only with the utmost difficulty that he was helped to a farm where stimulants were procured for him. Never afterwards would he permit any conversation about that vision of the sea; he shuddered when any reference was made to it.

This height-terror of Clough, induced by visual impressions of a special kind, recalls one phase of the dreamy mental state, that in which it reaches supreme terror with physical prostration; but a closer analogy to that state is perhaps to be found in the thoughts which arise during the inhalation of certain anæsthetics, and notably of nitrous oxide gas—thoughts which are nebular and voluminous, but which have never in them any tinge of fear or alarm, but are always inflated and exhilarating. When nitrous oxide gas is breathed in the pure state it abolishes volition and consciousness so rapidly that it is not possible for the person breathing it to observe distinct stages in its triumph over him; but when it is inhaled diluted with air its successive effects may be and have been many times marked and recorded. A momentary sense of suffocation accompanying hurried breathing is followed by feelings of fulness in the head, fixedness in the eyes, and increased resistance in the feet, suggesting that they are on the point of acting involuntarily in throwing the body forward; after these come giddiness and inability to maintain equilibrium, thrilling and vibrating sensations throughout the body, impairment of the power of accommodation in the eyes, and increased acuteness in the sense of hearing, so that distant and otherwise faintly heard sounds are judged to be near at hand; and then come the mental symptoms, which consist in convictions of emancipation, relief, and happiness, in grand and sublime ideas, which in their expansion seem to break down all barriers of doubt and difficulty, and to make a wish and its realisation one, and which, as they dissolve into delirium and confusion, are accompanied by extreme susceptibility to suggestions from without and automatic movements, such as the rapid repetition of a gesture or the vehement shouting many times over of some word or phrase, symptoms which finally merge into convulsive spasms and complete insensibility. It is at the point where the habitual control or check of the highest centres is withdrawn, and where subordinate centres are free to indulge in unwonted activity, that the expansive dreamy thoughts and exalted feelings present themselves in the progress of nitrous oxide gas intoxication. These thoughts or feelings are probably present in all who inhale the gas, and they are always of an agreeable character, for patients sunk in profound melancholia who have had nitrous oxide gas administered have allowed on their recovery from its effects that they had forgotten their misery for a little, had felt lively and like themselves again, or had even had a foretaste of heaven. But these thoughts and feelings, although always agreeable, vary vastly in character, and range from a simple sense of well-being and enjoyment up to the most magnificent conceptions, their complexion and amplitude being apparently determined a good deal by the personal equation. In persons of average mental calibre they are pleasant and stimulating, but in no way remarkable; but in persons of superior intellectual power they become thrilling and apocalyptic. A working man who inhales the gas intimates on his recovery that he felt very happy, just as if he had had a little too much beer, and a philosopher announces that the secret of the universe had been, for one rapt moment, made plain to him, but only to be swallowed up again in returning consciousness.

The expansive and stupendous nature of the dreamy thoughts induced by nitrous oxide gas in persons of superior and trained intellect is well exemplified in the researches of Sir Humphrey Davy on this gas—researches which, although they were carried out a hundred years ago, have not been surpassed in interest and value by any since made in the same department, even with all the aids of modern scientific apparatus. Describing the effects on himself of long-continued inhalation of the dilute gas Sir Humphrey Davy said: "My emotions were enthusiastic and sublime. I endeavoured to communicate the discoveries made during the experiment, but my ideas were feeble and indistinct; one collection of terms presented itself, and with the most intense belief and prophetic manner I exclaimed, 'Nothing exists but thought; the universe is composed of impressions, ideas, pleasures, and pains.' When I was awakened from this semi-delirious trance indignation and pride were the first feelings produced by the sight of the persons around me." On another occasion Davy remarks: "The sensations were so intense and pure as to absorb existence, and I fell into unconsciousness." But Davy experimented not merely on himself but on his friends with nitrous oxide gas; and as among these friends were Coleridge, Southey, Edgworth, and Dr. Roget we have in their observations the best possible evidence as to the operation of the gas on the mental faculties of men of high intellectual endowment. Well, that evidence is uniformly to the effect that the gas induced delicious feelings and heroic or stupendous thoughts. Indeed, of all anæsthetics nitrous oxide gas seems to be definite and uniform in the emotions and dreamy thoughts it induces in cultivated people, and therefore in the lines and order of its invasion of the higher nerve centres in them. The emotions are always pleasurable, the thoughts are in nine cases out of ten connected with some great discovery, some supposed solution of a cosmic secret. A medical man upon whom my former colleague, Dr. Mitchell, experimented with nitrous oxide gas imagined before becoming unconscious that he had made a most important discovery explaining the whole action of the gas; and Dr. Mitchell himself had repeatedly the same experience, his mind being seized by expansive ideas which, while they lasted, made all dark things clear. So vivid is the impression as to the reality of the ideas met with in the vestibule of nitrous oxide gas anæsthesia, and as to the genuineness of the insight they give, that many attempts have been made by sudden interruptions of the inhalation and by strenuous exertions of will-power to hold and capture them, it need scarcely be said without success. We might as well look for phosphorescence on the sea in the blaze of midday sunshine as hope to reproduce such dreamy mental states in the full light of objective consciousness. Nothing but a vague remembrance that they have flashed across the mind remains when waking life is resumed, and endeavours to recall them or grasp them in passing, when not wholly futile, are apt to prove ludicrous in their results. I daresay many of us recollect the story of the professor who, having experienced a magnificent thought in the early stage of chloroform inhalation, resolved that he would by one bold sally lay hold of it and so read the riddle of the world. Having composed himself in his easy chair in his study,

Digitized by Google

with writing materials at hand, he inhaled the chloroform, felt the great thought evolve in his mind, roused himself for an instant, seized the pen, wrote desperately he knew not what, for even as he did so he fell back unconscious. On coming to himself he turned eagerly to the paper, to find inscribed on it in sprawling but legible characters the secret of the universe in these words, "A strong smell of turpentine pervades the whole."

In rabbits the inhalation of pure nitrous oxide gas produces after brief excitement plunging convulsions, which have been said to be most marked on the right side and to be accompanied by drawing of the head to the right, but as regards the human subject I have only been able to find one case in which the invasion of the symptoms caused by inhalation was clearly unilateral. In that case the first physical effect noticed was a difficulty in moving the extensor muscles of the left arm, after which there came loss of power over the flexor muscles of the same arm, and then over the muscles of the other arm.

As the effects of asphyxia by submersion in water of an animal or human being are, as regards the higher nerve centres, not very dissimilar from those of the inhalation of an anæsthetic, we should expect to find during drowning some dreamy mental states analogous to those which attend the inhalation of an anæsthetic. And in this respect our expectations would be well founded, for it is even popularly believed that as life ebbs in drowning there is passed before the mind a panoramic review of its whole history, which we shall have no difficulty in recognising as a dreamy mental state. I am aware, of course, that the possibility of this panoramic review has been denied, and that many all but drowned witnesses have borne negative testimony as regards it and have represented their drowning thoughts as being of the most commonplace sort and occupied mainly with the weeds, pebbles, or sand that were seen around. I have no doubt the statements made about it have been greatly exaggerated, and that nothing like a complete picture of life ever passed before the mind under such circumstances; but still I am inclined to believe that very voluminous mental states do generally accompany drowning. The weight of evidence is in favour of them. Sir Francis Beaufort, in a letter published in the autobiography of John Barrow, described what happened to him when he was preserved from being drowned, when "every incident of his former life seemed to glance across his recollection in a retrograde succession, not in mere outline, but the picture being filled with every minute and collateral feature, each act of it accompanied by a sense of right and wrong." And since Beaufort's time many persons rescued from drowning have given an account of their expiring thoughts substantially the same and in harmony with what we are sometimes told of panoramic reminiscences in dreamy mental states. A domestic servant who consulted Dr. Hughlings Jackson, when communicating to him the warning of her epileptic seizures said: "It seems as if I went back to all that occurred in my childhood, as if I see everything so quick and so soon gone that I cannot describe it"; and dreamy mental states, apart from epileptic fits, have been recorded in which the whole coil of past existence seemed to be instantaneously unrolled.

I cannot further pursue what may be called the disguised forms of dreamy mental states, but I think, had I time, I should be able to show you that what used to be known in Scotland as second sight was sometimes only one of these states with a prescient intention.

I have touched upon the transitions which dreamy mental states undergo, on their associations and congeneric conditions, and I should like to say a few words about their consequences or the effects they exert on those who experience them. When they are linked with epilepsy or other serious nervous disease their effects are, of course, merged in those of the graver malady, and when they are an insulated ailment it may be questioned whether they have any effects that are clearly distinguishable. They carry with them, except when occurring while those who experience them are in positions of peril, no risk to life. They do not tend to self-perpetuation to anything like the same extent as epileptic fits, for in many instances they are, as it were, excrescences of childhood and youth, and wear themselves out in middle age. Even when they cling for life, it is often impossible to attribute to them pernicious results; and yet in many cases they do, I believe, have consequences of a painful and crippling description.

That dreamy mental states may persist throughout life without appreciable detriment to body or mind is, as has been said, undoubtedly true, but the same thing is true of epilepsy, which does occasionally go on into extreme old age without perceptible impairment of intellect or general health. It is sometimes even hinted that epilepsy, or the *morbus sacer*, is advantageous to intellectual development. We are told that Julius Cæsar and Mahommed and Marlborough and Napoleon and Wellington were epileptic, and are led to infer that that disease is almost an essential condition of great military genius, and the names of Molière and Sheridan and Balzac and Flaubert and other eminent writers who have been epileptic are mentioned in order to suggest that that disease is sometimes a valuable ingredient in literary talent. But a strict examination of all such cases brings out the truth that when the epilepsy did not come late in life, as a result of cerebral wear and tear, it did not promote, but to some degree marred, the genius or ability on which it was grafted. No doubt cases are encountered in which lifelong and violent epilepsy has proved not incompatible with great and sustained mental vigour. I have known a magistrate who at eighty years of age was a model of shrewdness and industry, and was still taking an active part in county business, and who had from puberty suffered from epileptic fits at short intervals; and there are, I believe, men similarly afflicted now filling important public positions with usefulness and distinction. Dostoieffsky, the great Russian novelist, was from youth subject to epilepsy of the worst type, and yet, notwithstanding this malady and intolerable hardships endured during imprisonment, penal servitude in Siberia, and enforced military service, he lived to the age of sixty, and went on to the end producing novels which will make his name live for ever, and in one of which he has delineated with minute observance and rare fidelity the symptoms of his own disease.

But such cases are exceptional. The rule is that epilepsy is a blighting, a crippling, a destroying disease. Our asylums, workhouses, prisons, and hospitals are full of the débris of its storms, and the flotsam and jetsam left by these may now and then be recognised floating hopelessly in the stream of population in our streets. And so, if dreamy mental states may coexist with brilliant intellectual powers, with robust health and energetic character, they may also on the large scale tend to undermine the mental and bodily constitution. It is difficult to gauge their effects. Even when occurring in great men they may to some extent limit the greatness to which they are attached; and in ordinary men they do assuredly sometimes blunt the fine edge of talent and induce dulness and stupidity or lower the breaking strain of the brain. When they occur at wide intervals their effects are probably immaterial; they are so slight and fugaceous as to escape notice. But when they come very frequently or in batches I have seen depression, mental torpor, and even temporary dementia resulting from them. They tarnish for a time the brightness of the brain and reduce the power of resistance of those who suffer from them, to other morbific agencies. John Addington Symonds, the historian of the Renaissance, suffered from dreamy mental states which left on him discernible traces. "Suddenly in church or in company," he said, "when I was reading, and always, I think, when my muscles were at rest, I felt the approach of the mood. Irresistibly it took possession of my mind and will, lasted what seemed an eternity, and disappeared in a series of rapid sensations which resembled the awakening from anæsthetic influence. One reason why I disliked this kind of trance was that I could not describe it to myself. I cannot even now find words to render it intelligible. It consisted in a gradual but swiftly progressing obliteration of space, time, sensation, and the multitudinous factors of experience, which seems to qualify what we are pleased to call ourself. In proportion as these conditions of ordinary consciousness were subtracted, the sense of an underlying or essential consciousness acquired intensity. At last nothing remained but a pure, absolute, abstract self. The universe became without form and void of content. But self persisted formidable in its vivid keenness, feeling the most poignant doubt about reality, ready, as it seemed, to find existence break as breaks a bubble round about it. The apprehension of a coming dissolution, the grim conviction that this state was the last of the conscious self, that I had followed the last thread of being to the verge of the abyss, and had arrived at demonstration of eternal Maya or illusion, stirred, or seemed to stir, me up again. The return to ordinary conditions of sentient existence began by my first recovering

Digitized by Google

the power of touch, and then by a gradual though rapid influx of familiar impressions and diurnal interests. At last I felt myself once more a human being, and although the riddle of what is meant by life remained unsolved I was thankful for the return from the abyss, the deliverance from so awful an initiation into the mysteries of scepticism."

These subtly analysed experiences of Symonds were not, as one of his critics imagines, an efflorescence of the meditativeness and introspectiveness of his nature, but unmistakably dreamy mental states, and dreamy mental states, too, which left a permanent mark or blemish upon him. His achievements, as he has himself declared, fell far short of his own justifiable anticipations and of those of his friends, and throughout life he was haunted by melancholy and by painful but concealed misgivings as to his own weakness. "I feel so weak," he complains, "so unable to take hold of any subject"—and this was long before his pulmonary trouble commenced. "I wish and cannot will," he again exclaims; "I cannot concentrate myself on an end of action." There was, it must be admitted, something lacking in him, a disarray of the faculties, constant lassitude, and uncertainty as to the path to pursue. His life has been described as a great spiritual tragedy, and it was so apparently because his highest nerve centres were in some degree enfeebled or damaged by these dreamy mental states which afflicted him so grievously.

Seeing, then, that dreamy mental states—although occasionally an appanage of genius and often innocuous—sometimes lead up to epilepsy or insanity, sometimes are one of a series of morbid events, and sometimes impair the faculties of those who suffer from them, they are surely worthy of medical observation and research. Especially in children and in the young should they be sought for and studied. If we want healthy and vigorous men and women we must begin with the babies; and if we want strong and stable brains we must see that their foundations are well and truly laid in the springtime of life. Flaws then overlooked may cause disastrous subsidence long after, and as dreamy mental states are flaws I advocate their detection if possible while they are still remediable. I do not suggest that mere children should be promiscuously subjected to crooked questionings, should have strange fancies put into their heads, or should be encouraged in introspection; but I do counsel that when children exhibit anomalous nervous symptoms—forgetfulness, lethargy, paroxysms of passion, immorality, tremors or odd movements or tricks, habit spasms, insomnia or headaches—the possibility of dreamy mental states being present should not be overlooked. A few skilful exploratory queries by the medical man will generally bring them to light where they exist, even when they have been scrupulously hidden away, and their discovery will be a great relief to the little patient and a guide to treatment.

As regards the treatment of dreamy mental states, it need only be said that it does not differ from that of cerebral neurasthenia and epilepsy. In almost all cases in which these states mount to such intensity as to demand treatment there is a reduction in the standard of general health and inferentially abnormal nutrition of the brain; and it would seem, indeed, that they depend on the reduction of cerebral nutrition to a lower level in whole or in part, and to an attendant increased instability in the brain tissue. In those who suffer from them habitually they become aggravated in character during periods of ill health and debility, and in town-bred children they are often connected with anæmia and excessive mental fatigue, and occasionally in the case of boys—though not, I believe, as frequently as might be imagined—with self-abuse. Rest and liberal nourishment rarely fail to alleviate and sometimes remove them altogether; but the rest must be adequate and the nourishment wisely chosen. A diet too rich in animal food has seemed in one case in which I have seen it tried to make dreamy states worse than they previously were. This is, indeed, what we might have expected. Shakespeare, in "Twelfth Night," makes Sir Andrew Aguecheek say, "I am a great eater of meat, and I believe that does harm to my wit"; and, whatever the effect of a liberal diet of animal food may be upon the healthy understanding, there can be little doubt that it is prejudicial to the mental power of epileptics. Just twenty years ago one of my colleagues, Dr. John Merson, carried out at the West Riding Asylum in a masterly way a series of observations bearing on this point. He placed two groups of epileptic patients on a nitrogenous and farinaceous diet respectively for a fixed period, and then for a like period he changed the dietary of the two groups, giving those patients who had had a farinaceous diet a nitrogenous one, and those who had had a nitrogenous diet a farinaceous one. The patients on whom he experimented were of a chronic and confirmed class—patients in whom long-continued epilepsy had resulted in mental deterioration; and yet even in them marked results were obtained. In fourteen out of twenty-four cases there was a decided decrease in the number of fits during the farinaceous diet, and in a very considerable number of cases it was observed that soon after the nitrogenous diet was commenced mental dulness and stupidity supervened, the patient passing into a state of hebetude, which only disappeared when a farinaceous diet was again resorted to. Quite recently Dr. Sydney Short of Birmingham made observations on the same subject, and found that in a number of epileptic patients, also of a chronic class and inmates of the City Infirmary, a reduction in the amount of meat in their diet was followed by a diminution in the number of fits.

What we now urgently need are accurate and extended observations on the influence of diets of various kinds, including and excluding several classes of constituents, in epilepsy and allied conditions, and experiments, scientifically devised and carefully guarded, with drugs. We possess remedies which have elective affinities for certain nerve centres, and which, therefore, promise to be useful in epilepsies of certain kinds; and for my part I will not believe that there is any finality in treatment, or that we have not in store for us the discovery of means of dealing with epilepsy and its allies even more potent than that medicine which Sir Charles Locock with such happy perspicuity placed in our hands as a weapon against them, at the very time when it had been omitted from the London Pharmacopœia because of its supposed uselessness and inertness. It is disheartening to reflect, however, that so little is being done, and that the material at hand is not more largely utilised. There are in our asylums and workhouses to-day enormous numbers of epileptics, the majority of whom are, I believe, as far as medical treatment is concerned, left to jolt down the hill of fatuity, headlong and heedlessly or with only the temporary application of the bromide brake now and then.

The fact that dreamy mental states are sometimes at first and to some extent under voluntary control, so that they can be induced or arrested, affords ground for the hope that well-ordered education and mental discipline will yet be made to contribute largely to brain health. Hitherto the education of the schoolmen with all its advantages, which I would be the last to disparage, has, alas, been responsible for much cerebral sorrow and ruin. Let us hope that education, when carried on on physiological lines, will conduce to peace and stability in the higher nerve centres. Let us hope also that a further investigation of the moral treatment of disease will put us in possession of methods of controlling mental metabolism—if I may coin the term—more powerful and exact than any as yet devised. We shall some day perchance be able by certain courses of study to massage the brain as we now do the body, and by certain definite exercises to bring successively into hygienic activity all the faculties of the mind, as Schott now does the muscles of the trunk and limbs. Gentlemen, I fear I have by my prolixity induced in many of you dreamy states of a purely physiological kind. I can only trust that they have not been of a disagreeable complexion and will leave you disposed to extend to me the indulgence I feel I require.

THE REGISTERED NURSES' SOCIETY.—The first annual meeting of this society, whose offices are at 269, Regent-street, London, was held, by the invitation of the Duke and Duchess of Abercorn, at Hampden House, on Saturday last. The chair was taken by Dr. Bedford Fenwick, treasurer, and the report of the committee showed that the society has achieved success in its first year of working. It was formed in order to enable the public to obtain the services of registered trained nurses, it being an essential condition of membership that every nurse must have worked for at least three years in hospitals, and must possess the highest professional qualifications and personal character. The nurses obtained their entire earnings, less a deduction of 7½ per cent. to cover expenses of management. That the society has met a public want is evident from the fact that a large number of applications for nurses have been made that could not be supplied; while the average receipts of the sixteen senior nurses for fifty-one weeks' work (£111 12s.) are a proof of the benefit of the society to its associates.

The Croonian Lectures,

BEING A

CONTRIBUTION TO THE HISTORY OF THE RESPIRATION OF MAN.

Delivered before the Royal College of Physicians of London on June 18th, 20th, 25th, and 27th.

BY W. MARCET, M.D. EDIN., F.R.C.P. LOND., F.R.S.

LECTURE IV.[1]

Delivered on June 27th.

MR. PRESIDENT AND GENTLEMEN,—So far we have dealt with the phenomena of respiration as carried on in the ordinary course of life. I now wish to draw your attention to breathing under circumstances which are not of daily occurrence, the first of these being under the influence of diminished atmospheric pressure as met with on ascending into high altitudes. This subject is important not only physiologically, but also with reference to the modern treatment of phthisis.

It must be clearly understood that the carbonic acid expired is unconnected with the consumption of the oxygen taken in the previous inspiration, as the oxygen derived from the air is carried into the circulation by the hæmoglobin and there serves the purpose of heat production and metabolism; the carbonic acid produced in the tissues passes out into the blood and is ejected with the expired air. Thus it is impossible to tell when a certain volume of oxygen taken into the blood may reappear as carbonic acid. This point I wish to establish clearly, as I believe an objection to my work has been made on that score.

If experiments on the respiration of man could be continued for a length of time—say the whole day—then the volume of air breathed would certainly compare with the weight (or volume) of carbonic acid produced; but it is not possible to do this, and the only alternative is to repeat the experiment as often as possible throughout the day, and take the means of the volume of air breathed and carbonic acid produced—a method invariably adopted in my experiments. I do not claim a relationship between the oxygen inspired and the carbonic acid expired immediately afterwards, but I claim a relationship between the mean volume of air breathed and the mean weight of carbonic acid expired in the course of one day. On ascending a mountain the air pressure diminishes and the pulmonary ventilation increases, in order to aerate the blood to its full extent. Now, although the volume of air breathed increases on rising above the sea level, still the weight of that air falls; in other words, its volume, reduced to dryness, freezing point, and seaside pressure, diminishes. Hence it may be said that, as one ascends, a less weight or volume (reduced to dryness and standard temperature and pressure) of air is breathed for the production of a given amount of carbonic acid. For instance, if at the seaside a person inspires a mean of 4 5 litres of air and expires 0·375 gramme of carbonic acid per minute, or, what is the same thing, inspires 12 litres of air, corresponding to the emission of 1 gramme of carbonic acid, on rising to such a height that the atmospheric pressure falls by one-fourth its amount at the sea level, the volume of air breathed corresponding to 1 gramme of carbonic acid will not exceed the original 12 litres by one-fourth, and thus become 15 litres, but will be less than 15 litres. It must be understood that the volumes of air breathed (reduced) decrease at increasing altitudes, a fact first published by a Swiss gentleman, Dr. Mermod, in 1875, and which I confirmed a few months later with observations made at much greater altitudes, his experiments being unknown to me at the time. A number of experiments made on the Peak of Teneriffe have also shown me conclusively that in perfect health the amount of carbonic acid expired remains unaltered with increasing altitudes, at any rate up to about 12,000 feet. According to Dr. Mermod, on the other hand, it becomes greater on rising above the sea level. On this point we therefore disagree. Discarding for a moment the idea of the influence of altitudes, it is well known that when the temperature of the atmosphere falls a greater volume of air is breathed and more carbonic acid expired, but the volume of air breathed for the emission of a certain weight or volume of carbonic acid is proportionately less; hence it appears that a fall of the atmospheric temperature gives rise to the same kind of effect on respiration as increasing altitudes without change of temperature. My earliest experiments made on the Alps were all attended with a fall of temperature at increasing altitudes, this circumstance necessarily producing an increased combustion in the body in order to overcome the action of the cold; it was therefore impossible by this means to determine the exclusive influence of atmospheric pressure on respiration, hence the necessity of selecting for these experiments a mountain of sufficient height near the tropics where one might expect to find the temperature fairly equal at different altitudes. With this object in view I spent three weeks on the Peak of Teneriffe in the summer of 1878, selecting for this inquiry four stations varying in altitude. The temperatures differed but very slightly at the four stations, though somewhat higher at the lowest, but there was no cause for any marked influence of temperature on the formation of carbonic acid. The air was expired into an indiarubber bag of known capacity, and a sample of the air was shaken with baryta water in a glass cylinder. The fluid, having absorbed all the carbonic acid, was afterwards collected in bottles, one for each analysis, and carefully stoppered, the final analysis being made at a subsequent period. In the following results every figure is the mean of the number of experiments entered in parentheses, the table showing the number of litres of air expired (reduced to dryness, freezing point, and seaside pressure) for 1 gramme of carbonic acid expired:—

—	Litres.	Temperature.	—
Seaside	12·0	75·7° F.	(20)
Guajara (7090 ft.)...	11·6	69·6° F.	(21)
Alta Vista (10,700 ft.)	10·4	64·0° F.	(20)
Foot of terminal cone (11,740 ft.) ...	10·3	64·0° F.	(5)

The difference is not great, still for 10,700 ft. it amounts to 1·6 litres; hence one-eighth less air was required at the two higher stations to produce through the respiration the same amount of carbonic acid as at the seaside. In other experiments made on the Col du Géant the reduction for an increased altitude of 9800 ft. amounted to about one-fifth in my own case, and rather more than one-twelfth for a young companion. On other occasions at various altitudes, from 8115 ft. to 13 680 ft., the mean height, 11,256 ft., gave a mean reduction of 2·03 litres of air breathed for 1 gramme of carbonic acid produced. These experiments show clearly that the aeration of the blood takes place more readily under diminished pressures than at the seaside, which is not easily accounted for. Paul Bert observed that the blood of various animals forwarded to Paris from the town of Mexico, situated at an elevation of 7480 ft., had the power of absorbing considerably more oxygen than the blood of similar animals kept in Paris, and concludes that the Mexican blood contained more hæmoglobin. This may be correct, but such a character could only be acquired after a number of years, perhaps of generations, while in my experiments the effect was produced, if not immediately, certainly after a few hours, when no change in the constitution of the blood could possibly have taken place. Frankland found that candles burn more brightly in air partially exhausted by an air pump than in the surrounding atmosphere, and concluded from this experiment that the molecules of oxygen have a greater mobility in the rarefied air. The more ready passage of oxygen into the blood at the lungs on reaching a high altitude may be due to a similar cause, but I cannot think that it is in any way connected with an increase of hæmoglobin.

As regards the medical aspect of the question, with reference to the treatment of phthisis in high winter stations, as Davos and St. Moritz, people residing there must live under circumstances facilitating the aeration of their blood, and I have no doubt that this is a primary and important cause of the beneficial effects produced. The extreme cold experienced must also be beneficial, since cold reduces the volume of air that has to be inspired for the production of a

[1] Lectures I., II., and III. were published in THE LANCET of June 22nd and 29th and July 6th respectively.

Digitized by Google

given amount of carbonic acid, so that both altitude and cold join in facilitating the respiratory phenomena. There is another experiment of Frankland which throws light on the circumstance that cold is so little felt on high winter stations. He found that if a platinum wire carried through an air pump receiver was made red-hot by an electric current it rose to white heat when the air pressure was reduced in the receiver, although the source of heat remained unchanged, from which he concluded that rarefied air removed less heat by conduction than the same air under atmospheric pressure. In accordance with this observation Frankland accounts for the fact that cold is felt less than might have been expected in the still air of Davos, from the circumstance that the lightness of the air checks the removal of heat from the body by atmospheric conduction. This view gains support from the statement of Paul Bert, in his book on barometric pressures, that compressed air has a tendency to produce a sensation of cold, although the temperature of the compressed air chamber may be higher than that of the external air, and with persons subject to the impression of cold this effect of increased air pressure is observed to become greater the longer the exposure and the higher the pressure. I, therefore, cannot help believing with Frankland that increased lightness of the air, acting inversely to increased pressures, assists in accounting for the remarkable fact that patients at Davos are so little troubled with the intense cold. An easy respiration at great altitudes is in a great measure the result of training; thus, while practised climbers easily ascend Mont Blanc, tiros, after about 10,000 ft. are attained, have to stop frequently for a few seconds to take breath, and often give way to fatigue or to a sleepy sensation or mountain sickness. Perhaps the most remarkable illustration of the influence of training is shown in the case of Mr. Whymper, who, having fought his way slowly and patiently to the summit of Chimborazo in spite of the suffocating effect of the low atmospheric pressure, experienced no difficulty whatever in repeating the same ascent six months later, having been engaged meanwhile in explorations at great altitudes in the Andes.

It may be remembered that in my last lecture I traced a connexion between "volition" and respiration; it will now be interesting to observe the effect of low atmospheric pressure on volition. Paul Bert submitted himself to low pressures in a closed chamber. At a pressure of 17·5 in. of mercury, having attempted to whistle, he found it impossible to do so; at 17 in. he suffered from dizziness, which recurred at 16·6 in.; at 16·4 in. he felt rather unwell, and, having counted 28 pulsations at the wrist in 20 seconds, found great difficulty in multiplying that figure by 3. These statements show that Bert experienced in a marked degree what we might call want of power to respond to volition under that low pressure. When the pressure had risen to 22·2 in. he began to recover his ability to whistle. Is not this an illustration of the action of oxygen towards promoting the power of the will?

A more remarkable illustration of the effect of a deficient supply of oxygen towards the suspension of the action of volition is found in the account given by Mr. Glaisher of his balloon ascent with Mr. Coxwell on Sept. 5th, 1862, when, at an elevation of 29,000 ft., the balloon still rising rapidly, he lost consciousness. Allow me to extract *verbatim* from Mr. Glaisher's book, "Travels in the Air":—"At 1 o'clock and 51 minutes the barometer read 10·8 inches. After this I could not see the column of mercury in the wet-bulb thermometer, nor the hands of a watch, nor the fine divisions on any instrument. I asked Mr. Coxwell to help me to read the instruments. In consequence, however, of the rotatory motion of the balloon, which had continued without ceasing since leaving the earth, the valve line had become entangled, and he had to leave the car and mount into the ring to readjust it. I then looked at the barometer, and found the reading 9¾ inches, still decreasing fast, implying a height exceeding 29,000 feet. Shortly after I laid my arm upon the table possessed of its full vigour, but on being desirous of using it, I found it powerless; it must have lost its power momentarily. On trying to move the other arm I found it powerless also. Then I tried to shake myself and succeeded, but I seemed to have no limbs. In looking at the barometer my head fell over my left shoulder. I struggled and shook my body again, but could not use my arms. Setting my head upright for an instant only, it fell on my right shoulder; then I fell backwards, my back resting against the side of the car, and my head on its edge. ..... As in the case of the arms, so all muscular power was lost in an instant from my back and neck. ..... In an instant intense darkness overcame me so that the optic nerve lost power suddenly, but I was still conscious, with as active a brain as at the present moment while writing this. ..... While powerless I heard the words 'temperature' and 'observation,' and I knew Mr. Coxwell was in the car speaking to and endeavouring to rouse me before consciousness and hearing had returned. I then heard him speak more emphatically, but could not see, speak or move. ..... Then the instruments became dimly visible, then Mr. Coxwell, then shortly I saw clearly, next I rose from my seat and looked around as though waking from sleep. ..... I then drew up my legs, which had been extended, and took a pencil in my hands and began observations. ..... It is probable that three or four minutes passed from my hearing the words 'temperature' and 'observation' till I began to observe"

The case of Mr. Glaisher is very remarkable if taken in conjunction with the fact, which I look upon as proved experimentally, at all events as far as an experiment can go for the present, that the exercise of volition requires the direct action of oxygen on the brain centre concerned. In the present instance the conception of volition was not in abeyance, as Mr. Glaisher could direct his will as he pleased, but there was no response; he wished to move his limbs and could not. Hence as far as can be concluded from the experiment of Bert and the narrative of Mr. Glaisher the conception of volition does not require oxygen, but the manifestation or response of volition cannot be carried out without it.

Another effect of rarefied air when accompanied by intense cold is that it appears to check the mental faculties, producing the sensation of drowsiness so often experienced on high mountains.

Thus far the effects of diminished pressure have been considered; those produced by increase of pressure have been the subject of many inquiries. Paul Bert assimilates the effect of an increased atmospheric pressure to the respiration of a proportional addition of oxygen at ordinary pressure; this view, however, does not take into account the cooling influence of compressed air.

From Dalton's law the solubility of gases increases proportionately with the pressures, hence under increased atmospheric pressure a little more oxygen should be absorbed by the blood, and this is found experimentally to be the case. There is also a slight increase of carbonic acid expired, which, according to Bert, may be observed up to about five atmospheres, the maximum increase occurring at about three atmospheres. At pressures above five atmospheres oxidation falls below the normal, the excess of oxygen arresting rather than exciting combustion. Quoting from Bert's book, this cessation of the oxidation of tissues from excess of oxygen takes place in all living tissues; even seeds no longer germinate when maintained under pressure. Dr. G. von Liebig, from experiments made in 1875, found that at pressures of about 40 5 in. of mercury the carbonic acid expired was increased by less than 1 per cent. These experiments correspond with others I had occasion to make, when atmospheric air was inhaled in which one-third was replaced by oxygen gas. According to the views advocated by Bert, this artificial air, containing 43 per cent. of oxygen instead of 20 9 per cent., would be equal to a pressure of about two atmospheres. In every experiment there was a large increase of oxygen absorbed by the blood, an increase which very clearly exceeded the absorbing power of the blood corpuscles, but the carbonic acid expired was but slightly, and in some cases not at all, in excess of the normal, thus illustrating very forcibly the remark made in my first lecture, that it is not the oxygen which by offering itself to the blood and tissues promotes the tissue changes. The slight excess of carbonic acid expired when the body is subjected to increased atmospheric pressure is probably due to the greater conducting power of compressed air, which withdraws heat from the body. Dr. C. T. Williams, in his book on "Aerotherapeutics," states that in certain cases of asthma decided relief was obtained by the use of the compressed air bath. I account for this favourable action of compressed air in asthma by regarding the bath as a method of training the respiration. Dr. Williams observed that a larger volume of air was breathed after the use of the bath than before. This increased pulmonary ventilation will obviously assist in aerating the blood and ridding it of its carbonic acid, the percentage of which in the expired air would, I doubt not, be found lower than normal, thus assimilating the phenomenon to one of unconscious forced breathing.

To pass on to another subject. Allow me to draw your attention to the effects of the inhalation of carbonic acid,

Digitized by Google

and first of all to the phenomena observed on rebreathing one's own expired air. I made experiments by rebreathing for five minutes 35 litres of air contained in a bell jar suspended over salt water. The air was inspired through nasal cannulæ connected with the roof of the receiver, and expired by the mouth into the bell jar in the usual way. At each inspiration the bell jar fell slightly, and rose at the following expiration. Little or no distress was felt during the first three or four minutes, though in the last minute a slight feeling of want of air was occasionally experienced, but this varied with different people. Tracings of this kind of respiration show that as rebreathing continues the respiration becomes deeper and more rapid, while the direction of the tracing is not quite horizontal, but has invariably a tendency to fall; this is due to the absorption of oxygen and carbonic acid in the blood and the consequent diminution of the volume of air in the receiver. The history of the phenomenon is very simple. Oxygen is consumed from the air and partly converted into carbonic acid, while the remainder is used up in other ways. Under ordinary circumstances the carbonic acid produced is exhaled; but in this case it accumulates in the bell jar, and, being inhaled, prevents the free diffusion of the gas from the blood into the lung cavity, and therefore carbonic acid becomes retained in the blood in gradually increasing quantity. Moreover, the amount of oxygen in the air inspired falls rapidly, and this air therefore becomes less and less fit to maintain life. In my inquiries five persons submitted to a total of forty-two experiments, each of which consisted of four stages. In the preliminary stage the carbonic acid was determined in normal respiration. In the second stage 35 litres of atmospheric air were rebreathed for five minutes and subsequently analysed. Immediately after rebreathing, the air expired was diverted into another bell jar, till about 35 litres had been expired, after which the air given out from the lungs was collected separately for a further period of four or five minutes, both quantities being analysed for carbonic acid. The broad results obtained from this inquiry were as follows: 1. On rebreathing air in a closed vessel, less carbonic acid is expired in a given time than in ordinary breathing, a certain proportion remaining absorbed in the blood. 2. When fresh air is taken into the lungs immediately after rebreathing, the volumes of air breathed and carbonic acid expired are greater than in ordinary breathing. 3. When after the rebreathing stage fresh air has been inspired for five or six minutes the blood has recovered its normal state of aeration, and given out the whole of the carbonic acid which has been absorbed in the rebreathing stage. Paul Bert has shown that animals, when left to die in closed vessels, are not asphyxiated from carbonic acid, but die solely from want of air, the phenomenon being the same as if they were submitted to diminished pressures corresponding to the proportion of oxygen left in the receiver in which they were confined. In five of the above rebreathing experiments the mean percentage of the original oxygen which had disappeared was 19·2; the pressure corresponding to this reduction of oxygen would be 24·23 in., equal to an altitude of about 7480 ft.; such a low altitude explains the absence of any difficulty or distress in the breathing. On one occasion rebreathing was continued till the air in the bell jar contained 13·64 per cent. of carbonic acid and only 5·40 per cent. of oxygen, this percentage of oxygen corresponding to a pressure of 7·74 in. of mercury. The person under experiment felt very giddy, and the vision was obscured by a dark mist. It is difficult to state the limit of altitude to which man can attain, because as he rises higher he needs less and less air; the secret of attaining to very great heights is training and time. Mr. Whymper reached an altitude of 20,517 ft. on the Chimborazo, and Mr. Conway to 22,600 ft. on the summit of the Pioneer Peak in the Himalayas.

Returning to the consideration of the influence of carbonic acid on respiration, it is often asked to what extent this gas can be breathed with impunity in the atmosphere. The subject has been investigated, amongst others, by Professor Emmerich and Dr. von Pettenkofer, who, in company with others, shut themselves up in a small vault of the Institute of Hygiene at Munich with bottles of liquid carbonic acid. Light was emitted from candles. The gas was allowed to escape from the bottles, and when the lights went out most of the visitors left the chamber. Professor Emmerich and Dr. Pettenkofer remained inside, and when seized with headache and discomfort took several samples of air and then left the vault none the worse for the experiment. The analysis of the samples gave a mean of 8 per cent. of carbonic acid, which proportion can therefore be breathed for a short time without producing any serious effects. Rabbits have, according to Professors Friedländer and Härter, withstood for more than an hour 34 per cent. of carbonic acid, and even 60 per cent. was breathed for three-quarters of an hour, after which cramp and coma set in; after being exposed for a quarter of an hour in this 60 per cent. mixture the rabbit quickly recovered in the open air.

ASTHMA.

Having said so much on respiration, allow me to offer a few remarks on a disease which is peculiarly one of the respiratory function—that is, asthma; and first of all, as an introduction to the subject, let us analyse the phenomenon of coughing. In coughing, a long breath is taken, which is exactly like a deep or forced inspiration, in which, as I have shown, a certain amount of carbonic acid is produced for work done, the oxygen being derived from that pre-existing in the contracting muscles, while a larger volume of carbonic acid is displaced from the blood by a purely physical process; but, though forced breathing is attended with but comparatively little work, in coughing the respiration is laboured, the muscles having to strain against the closure of the pharynx and forcibly expel the air from the lungs. This results in the production of an excess of carbonic acid; hence at the end of the expiration there is an increased amount of carbonic acid in the circulation. After the forced expiration of coughing a deep breath is taken to supply the blood with a fresh quantity of oxygen and rid it of the excess of carbonic acid produced, and this process goes on till the fit of coughing comes to an end; then deep inspirations and expirations follow till the blood is again perfectly aired and the carbonic acid in excess completely eliminated. It therefore appears that in coughing there is a tendency to a want of oxygen and a distinct excess of carbonic acid in the blood, which are conditions met with, though in a much intensified form, in asphyxia. Now asphyxia is occasionally productive of spasms of the glottis, as seen in some cases of recovery from drowning, and might not the momentary want of air produced by a bad fit of coughing be the cause of asthma in people who are subject to it? The following observation was made by a physician who at times had severe attacks of asthma, though usually in the enjoyment of good health. On Feb. 13th last, after taking a cup of tea at 2.30 A.M., loud wheezing and tightness of the chest came on, when a succession of forced inspirations had the immediate effect of arresting both the wheezing and tightness; a second attack the same night was averted in a similar manner. In this case the forced breathing returned to the blood the oxygen it was clearly in want of, while at the same time removing the carbonic acid.

I have shown in my third lecture that forced breathing is a means of supplying the centre of respiration with oxygen towards the respiratory phenomena; hence it appears to follow that a deficient supply of oxygen to the respiratory centres has also something to do with asthma. In keeping with these remarks it may be said that all circumstances productive of an excess of carbonic acid in the body, and therefore of a deficiency of oxygen, predispose to asthma. Cold and certain kinds of exercise do so pre-eminently, so does the ingestion of food, as happened in the case referred to above, where an attack of asthmatic coughing came on pretty regularly two hours after dinner, or at the time of the maximum production of carbonic acid from the meal. A bad attack of asthma usually sets in with a sudden loud dry cough, coming on in the evening or at night; then follows a bronchial spasm during inspiration and the acute feeling of suffocation. After fighting for breath for ten, twenty, and in some cases thirty hours the respiratory muscles become very tired, and also volition towards the respiratory effort. Moreover, the impediment to breathing prevents oxygen reaching the centres of respiration to promote the exercise of volition for forced breathing; hence the power of the will becomes less and less. It is difficult to reconcile the fact that some asthmatic persons find themselves better under lower atmospheric pressures, while others, on the contrary, suffer the moment they leave the sea level. This is apparently due to the circumstance that some persons take in oxygen more readily under low pressures, and others under high pressures. I cannot help comparing asthma in those who suffer under low pressures to a sort of mountain sickness—the higher they go the worse they are, and the moment they return into the lower plains the asthma passes

Digitized by Google

off as by magic. If mountain sickness can be prevented by training for the exercise of climbing under low pressure, why should not asthma also yield to the training of the respiration carried out by practising the respiratory movements wanted to carry the tidal air through the lungs to oxidise the blood and emit the carbonic acid, while imparting to the circulation a better tendency to work in perfect harmony with the respiratory requirements? Of all means of training the respiration I think cycling is the best. When a person first takes to cycling he is troubled with shortness of breath, his heart beats uncomfortably, and his legs get tired, but after some training these discomforts all disappear. Why should not people liable to attacks of asthma also train their respiration by such a kind of exercise—of course, on condition of the heart and lungs being in perfect health? Cycling exercise first of all increases the depth of breathing, and that without fatigue, as the respiratory movements are automatic; at the same time it will accustom the rider instinctively to take in at each respiration the volume of air required to aerate the blood and to eliminate a fixed proportion of carbonic acid, leaving in the circulation the precise amount compatible with health. In cycling volition has also a good deal to do towards exercising the motor centres to take in the exact volume of oxygen required for that kind of work. Persons who do not care for cycling out of doors can take the same description of exercise at home by means of a dummy cycle. My experience of the results of this treatment is unfortunately only limited to one person; in which case it has proved eminently successful. This person took to bicycle riding three years ago, first for pleasure and then on account of his health. He observed last summer that attacks of asthma to which he was subject had become very much fewer, having only suffered two since last October, both of these being brought on by exposure to cold. The tightness and wheezing which occurred every night have nearly entirely disappeared; his sleep, which for years had been restless and broken, has very much improved; and all this he ascribes in a great measure to the use of the bicycle.

Allow me, Gentlemen, to summarise shortly the Croonian Lectures for the present year. In the first lecture the oxygen of the atmosphere was shown to be the main agent of life, and Hermann's discovery that oxygen is an integral part of the tissues was appealed to with the object of explaining the remarkable tenacity of life of certain organisms—such as seeds. Next came an attempt to explain that it is not the oxygen of the air which, by offering itself to the tissues, produces the phenomena of metabolism, but that the living tissues call upon the oxygen to effect the changes they undergo. The influence of tissues as the prime movers in the matter was shown by the action of cold, which, through the nervous system, first increases their vitality and consequently their demand for oxygen, though when the cold is excessive it exerts an influence the reverse in its character. Muscular exercise invariably tends to the production of carbonic acid in excess; and this led to some remarks on the temperature of the body while in the act of ascending. It was concluded that with some people there is a slight increase and with others a slight fall of temperature. The second lecture was prefaced with a short allusion to past investigations on human respiration; then followed the history of the different forms of breathing, which were illustrated by tracings (reduced in size) taken directly from the person under experiment. Attention was also drawn to the interesting phenomena of the absorption of oxygen in the body independently of the formation of carbonic acid, and a number of analyses were quoted showing to what extent this absorption takes place. The third lecture was given up entirely to the influence of volition on the respiration. It was shown that volition towards any kind of muscular exercise, including forced breathing, is attended with the absorption of oxygen in excess, and that this oxygen is necessary towards the performance of volition, and, if necessary to volition, it must be taken up by the motor centres of volition. A remarkable effect on the development of muscular force by this charging of the motor centres with oxygen was shown to take place. Finally, an experiment was described in which, volition becoming tired out, the muscles refused to work, this experiment being in keeping with Mosso's discovery. The fourth lecture was devoted first of all to an account of the influence of climbing on the respiratory changes and on the state of the respiratory phenomena at high altitudes. Next, rebreathing and air breathed under pressure were considered, and it was explained that the effect of rebreathed air was apparently due more to the want of oxygen than the absorption of carbonic acid. After a few remarks on the effects of breathing mixtures of carbonic acid and common air the lecture was concluded with an allusion to asthma and a method of treatment suggested by the considerations which may be looked upon as the substance of these four lectures.

THE VARIETIES OF RHEUMATOID ARTHRITIS.[1]

BY R. FORTESCUE FOX, M.D. LOND.

THERE is no class of affections for which relief is more commonly and, I may add, more justly sought at mineral waters and baths than painful enlargements of the joints, particularly those to which the adjectives gouty, rheumatic, or rheumatoid have been attached. It is the object of this paper to present some typical examples of the complex group commonly known as rheumatoid or osteo-arthritis out of a considerable number that have come under my observation at Strathpeffer Spa, to describe by their aid the several varieties of disease at present united under that name, and to deduce if possible some conclusions as to their actual nature. The material at our disposal is clinical—post-mortem examinations are happily rare—and no light has, so far, been shed upon the subject by the method of experiment.

CASE 1.—A young woman aged twenty-four years was placed under my care in September, 1888, by Dr. Chalmers of Stirling, with the following history. There was no known tendency to rheumatism or other illness in the family. The patient had been quite well until eighteen years of age, when in the spring of the year "rheumatism" began quite quietly to show itself in the feet and hands, but without fever or confinement to bed. The catamenia had commenced late—at seventeen—only six months before the onset of the joint troubles; these had been always irregular, two, three, or four times only in the year, and it was stated that the pain, swelling, and stiffness of the joints had been usually worse for a week or more before the periods. In the six years that had elapsed before coming to the Spa the patient had resided in an exposed situation near the east coast of Scotland, and the affection had gradually involved not only the feet, hands, and wrists, but, latterly, the knees and elbows also. In September, 1888, she was obviously much out of health, there being frequent neuralgic headache, malaise, anorexia, profuse perspiration, sometimes confined to the back of the neck and head and to the hands, which were cold, clammy, and sodden with moisture. The pulse was 90 and the heart was normal. Severe pains were present in the joints and in the body generally; these were always worse at night. A course of baths considerably relieved the symptoms, and she remained much better for three months, when the complaint returned and gradually incapacitated her, although, with great energy, she continued her occupation as teacher in a bleak country-side, and was carried to and from the schoolhouse in the winter months. This was followed by a long period of confinement to bed, with cod-liver oil treatment, and considerable improvement in general health resulted. In the following February (1890) she returned to Strathpeffer, presenting the following condition. The hands still had a white, sodden, œdematous appearance; the finger joints, formerly so much swollen, were nearly natural in size, but two or three were slightly stiff; the wrists were uniformly swollen and nearly immovable; the elbow-joints were both swollen and stiff, the left being almost immovable; the feet were swollen and painful; and the knees, hips, and shoulders were practically unaffected. In July of the same year, the joints being quiet and the general health much improved under a prolonged course of Spa treatment, I broke down the adhesions in the stiff elbow under an anæsthetic. In February, 1895, thirteen years after the onset of the malady, this patient wrote that she was confined to her couch or bath-chair; both legs and the right arm were stiff from adhesions and were useless, but the arm on which the

[1] Read before the Hunterian Society, March 27th, 1895.

Digitized by Google

operation was performed five years ago remains a fairly movable and useful limb.

CASE 2.—A girl, a gamekeeper's daughter, had enjoyed good health until eleven years of age. No tendency to hereditary disease had been noted, excepting that her father, like most gamekeepers, had had rheumatism slightly. At that age she had influenza, with severe pains in the limbs and a skin eruption. Four months later, while going about during the summer of 1890, rheumatoid arthritis gradually set in, affecting, successively, the left hip and thigh, both hands, and the left foot. A year later (June, 1891) she sought relief at Strathpeffer, and her condition was then as follows. The patient was twelve years of age, tall, delicate, weak, anæmic, and subject to profuse perspiration. She had been growing quickly. The catamenia had not appeared. The right wrist was uniformly and evenly enlarged, painful and tender, with very limited flexion movement; the left wrist was similarly affected, but less so. There was in both wrists slight crackling on movement. The left ankle was slightly enlarged and tender. She remained for two months under Spa treatment, taking a course of douche baths in addition to sulphur waters internally; she left greatly benefited. In August, 1891, she returned; there were wasting of the interossei muscles and too great prominence of the styloid process of the ulna, the wrist remaining nearly stiff, but the inflammatory stage being confined to the middle joint of one finger. Three and a half years later (March, 1895) she wrote that she was quite well, but the right wrist remained stiff and swollen, and the one finger still affected.

These two cases illustrate the rheumatoid arthritis of young subjects, and it is, in my experience, in the young that the disease assumes its most severe and intractable, and, I would, add, typical, form. (See Figs. 1, 2, and 3.) A large number of joints are usually

FIG. 1.

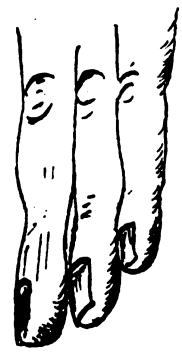
affected, and there are, from the first, profound debility, rapid heart, profuse perspiration, and progressive wasting. The articular symptoms vary according to the severity and duration of the malady. During the inflammatory stage, which commonly extends over several years, there is always swelling, usually (though not always) symmetrical and involving both the joints and the extra-articular structures. In the acute condition there are synovial effusion, heat, and extreme pain and tenderness. Mobility rapidly diminishes, and stiffness may ensue early in the case. Pain is present always and is referred not only to the joint but to the nerves and muscles. In the joint it is dull, aching, or burning in character when at rest; severe and acute on movement; and it is darting and lancinating when referred to the nerves. Neither season nor weather commonly affect the pains. In some cases it is specially noted that they are more severe in the hot days of summer; in others, especially in the early stages of the complaint, that the pains tend to subside in summer and return in winter. Increased stiffness is frequently complained of during a change in the weather, and it is usual for the pain to be more severe in the night-time, particularly from 3 to 5 A.M. The second period of the disease is marked by degeneration and atrophy both of joints and muscles. Certain joints are subject to occasional returns of inflammation, but the main condition now is one of atrophy, with stiffness and more or less—sometimes very little—deformity. Such deformity as exists is due to muscular wasting and subluxation of the phalanges rather than to lipping of the articular edges or osteophytic growths, which are rarely met with in rheumatoid arthritis of the young. The middle phalangeal joints, the wrists, and the tarsal joints seem to be particularly obnoxious to the disease, and are usually much swollen. Somewhat later in the disease one commonly finds several of the terminal phalangeal joints absolutely stiff and obviously atrophied. The joint is thinned and concave on the dorsal aspect, and covered by glossy skin, and yet I have seldom met with swelling or inflammation of these joints in rheumatoid arthritis; the fact of their becoming affected with simple atrophy is not without a bearing on the pathology of the disease. (See Fig. 4.)

Rheumatoid arthritis of the young is, in my opinion, a clearly outlined clinical variety of the disease. Out of forty cases of which I have full notes thirty-two are females—that is, four out of five; and of the eight males two should perhaps be excluded as gonorrhœa preceded the arthritis. The youngest of my cases was six years of age at the commencement of the disease. The average age is twenty-two years and a half; this is the age of catarrhal affections and of tubercle, not the age of adolescence or development, but the age at which the finished nervous and bodily powers are put to their first serious practical strain. It is also, therefore, especially in the female sex, the time of nervous and emotional tension and breakdown. In some cases (thirteen or fourteen out of forty) depressing illness preceded the arthritis, such as typhoid fever, great nervousness and weakness, influenza, suppurative otitis, double conjunctivitis, abscess of the right hand repeatedly lanced (in this case the disease began in the right thumb) dyspepsia and chronic diarrhœa, dyspepsia when at school in Germany, and exhaustion after childbirth. The exciting cause is stated in a good many (twelve) cases to be chill or cold, sitting on damp grass, &c., and in one case the shock of a railway accident. Certain localities, or rather climates, are favourable to the development of the disease, and eight of the forty cases came from the east coast or near the east coast of Scotland, particularly about the Firth of Tay. The following symptoms are noted as preliminary or pre-arthritic, and have some bearing on the nature of the disease: peculiar "want of animal heat" and a "sense of chilliness" (this was noted as continuing in one case for three years, and in another for some years, before the joints became affected, after which there was natural warmth; Sir Alfred Garrod has noted "languid circulation and cold extremities" as common in rheumatoid arthritis, but this common condition is not, I think, usually associated with the sensation of cold); pains under the balls of the toes and, as my friend Dr. Spender of Bath has noticed, pain at the root of the thumb; toothache-like pains in various joints—worse at night; numbness and aching in the fingers; heat and pain in the soles of the feet (a frequent observation); pains all over the body; flying pains, languor and sense of fatigue (several cases); pain, sweating, and restlessness; and pain and stiffness in the calves of the legs accompanied by dark blotches on the thighs. These are the symptoms recorded as existing for a variable time before the localisation of pain and swelling in the joints. Dr. Spender has dwelt upon the importance of recognising these early symptoms; and I have myself seen several cases in young people in whom the rapid pulse, localised sweating, neuralgic pains, and peculiar debility presaged, only too surely, the onset of this frightful malady. The following cases are typical of a somewhat similar condition met with later in life. (See Figs. 4 and 5.)

Digitized by Google



CASE 3.—A tall, robust, vigorous, married woman fifty-three years of age had suffered from no particular illnesses. Both parents were healthy and died when over eighty years of age. One brother died from phthisis, and a sister had had sciatica and muscular rheumatism. The patient was childless; a fibroid of the uterus had been discovered at forty, but had not inconvenienced her much, and the catamenia ceased naturally at forty-nine, since which time (four years) she had been subject to heats and flushes with occasional pains and swellings in the knees. At fifty-three years of age she contracted a chill when heated, and was laid up with severe pain in the left hip and wrist and to a lesser extent in the right ankle. The painful parts became swollen and she perspired profusely. Seven months later (October, 1892) she came for treatment to Strathpeffer. Both the knees were at this time greatly enlarged, in addition to the left wrist and right ankle. Although she was scarcely able to walk a course of warm douche baths were successfully given. In the following July she returned, reporting considerable improvement, but the knees still remained painful, and, indeed, rather more swollen, and there was much crackling on movement. Some of the terminal phalangeal joints, not obviously affected before, were becoming atrophied, with stiffness and glossy skin. (See Fig. 5) A full course of douche baths was ordered, in addition to sulphur waters internally, and in the following winter she took, by my advice a long course of arsenious acid with carbonate of iron. In June, 1894, she made a third visit to the Spa, reporting herself as much better and walking two miles. She was free from pain, excepting on damp days; the left wrist was almost absolutely stiff; there was dry crackling in the left thumb, and some of the fingers did not close properly. After further hot douching and massage a limited movement was obtained in the left wrist, and since then she had remained, but for the stiff joints, practically well.

FIG. 5.

Third, fourth, and fifth fingers of female aged fifty-four; eight months after onset of arthritis. Terminal joints stiff and atrophied, concave and glossy on the dorsal aspect. Nails longitudinally ridged and brown.

CASE 4.—A married woman aged forty-two came to Strathpeffer in June, 1888, having suffered from rheumatoid arthritis about twelve months. The family history showed no signs of rheumatism or gout, but one sister had died from phthisis at twenty-four. The patient, who had never had rheumatism before, was the mother of nine children, and the youngest, born when she was thirty-nine, she had nursed for fifteen months. The arthritis, for which no cause is assigned, came on in June, 1887, "simultaneously in all the joints," and confined her to bed or couch for nearly twelve months. On arrival at Strathpeffer the knees and hands principally were found to be affected, the former being very stiff, painful, and swollen, and the mid-phalangeal joints were becoming stiff and concave on the dorsal aspect. The general health was low, she being subject to frequent perspiration, especially of the hands, and acute pains. Although confined to the house and almost to bed, a course of waters was taken in 1888 and in the following year, on both occasions with benefit. Two years later (July, 1891) she returned, four years after the onset of the disease, presenting the following condition. The right hip-joint had been acutely affected, and was still much swollen and exceedingly painful on adduction and abduction. The disorganising process had gone on in the left knee, and a sudden attack of very acute pain on moving the joint (probably displacement of diseased cartilage) had been followed by almost absolute stiffness for the previous twelve months. The general condition had, however, improved; the hands were decidedly better, and the left wrist was stiff, but allowing the patient to use the sewing machine; she was, however, unable to walk or stand. After a prolonged course of douche baths I endeavoured to extend the left knee under an anæsthetic. It was fixed at an angle of about 120°, and so firm were the adhesions that it was with great difficulty I brought it to about 150° and put it up in a poroplastic splint. It is now three and a half years since the operation, and the patient has written stating that she is much better in health, that the perspirations have ceased, the hip and hands are much better, and although she still suffers occasionally from sharp pain in the left knee she can walk from half a mile to a mile.

The generalised rheumatoid arthritis of the climacteric epoch which these two cases exemplify is represented by thirteen cases out of a series of sixty-five. All, of course, are females, and the average age at onset is forty-eight years, the extremes being thirty-seven and fifty-four. In many cases the disease is certainly much less severe than in our first and much larger clinical group. Intermissions of one or two years are not very uncommon after the first onset, and after a few years comparative quiescence with localisation in one or two or a few joints is much more frequent than in arthritis of the young. (See Fig. 6.)

FIG. 6.

Right hand of female aged forty-nine; three years after onset of arthritis; wrist much affected.

There is at the same time less profound constitutional disturbance and thus a more favourable prognosis. In several of my cases the complaint has been almost or quite confined to the left side of the body. It is worthy of remark that this form of anthritis may be, and often is, complicated by any hereditary or other condition peculiar to the climacteric epoch in women. Thus gout in some form is not uncommon then, although entirely absent in earlier life; and more frequently there is a state of ill-health which it is difficult to name, and to which I referred at the International Medical Congress last year in these terms:—"A condition of deteriorated blood, loaded with waste products, frequently met with after middle age, but more particularly in women, and due apparently to some defect of metamorphosis or excretion. There is little or no organic disease, but the patient complains, it may be, of obstinate dyspepsia, acidity, shifting rheumatism, sciatica, or lumbago; perhaps cramps, tenderness and heat in the soles of the feet, or other ill-defined articular symptoms, and frequently headaches, cutaneous irritation and eczema. There is often in women a change in the symptoms after the climacteric, the articular pains and swellings becoming then more pronounced."

In climacteric arthritis prearthritic symptoms are very usual, such as neuralgic or shooting pains even for two or three years, burning in the soles of the feet, with or without profuse sweating, etc. In regard to the view advanced by Dr. Ord that the disease is induced by abnormal conditions or disturbance of function of the uterus or ovaries, the following notes may be added. Out of a total of forty-seven cases in women the catamenia are stated to have been irregular in five, there was fibroid tumour of the uterus in two cases, and ulceration and leucorrhœa in one case. The

Digitized by Google

pains were frequently stated to be unaffected by the catamenial period, but in two cases they were worse beforehand, in two other cases worse at the period, and in one case worse afterwards. Climacteric arthritis attacks married women much more frequently than single, the proportion in my cases being eleven to two, and the patients are, as a rule, mothers of children. Taking all my cases together (Groups 1 and 2) in which the arthritis affected married women, I find that twelve out of sixteen were mothers. In one case, that of a mother of nine children, the arthritis was said to be always better after childbirth, and in another the onset of the disease immediately followed upon childbirth. One of the severest cases of rheumatoid arthritis I have ever seen, and fatal after only four years, was that of a young married woman in whom the disease appeared twelve months after her marriage at twenty-three. The catamenia were regular and painless throughout, and there was no sign of uterine or ovarian disorder. It is worthy of remark that in many of Dr. Ord's cases the arthritis was not general, but localised, and therefore, in my view, to be clearly distinguished clinically from the disorder we have now under consideration. Furthermore, a large proportion of his cases occurred about the climacteric period, when, as Haygarth first noted in 1805, nodosities of the joints were most common. To these local and separate forms of arthritis I shall again allude.

The third variety or group is generalised rheumatoid arthritis in the old, senile rheumatoid arthritis, of which the two following cases are examples.

CASE 5.—A man aged sixty-five had been for forty years a gamekeeper on an estate situated in an exposed part of the Highlands. Coming of a healthy long-lived family he was himself a healthy man. He had never had rheumatic fever, but at fifty-one was affected with pleurisy from exposure, and since reaching the age of sixty he had had some slight rheumatism in the right thigh. For some years past the long hours and long fasts upon the hills, with exposure and fatigue, had broken his health, and the sense of duty inadequately done had preyed upon a naturally anxious and overconscientious mind. At sixty-five, therefore, he was obviously failing and depressed, bodily and mentally. At this time an accidental fall in April or May, 1891, was followed by a sudden attack of acute arthritis in both hands, feet, and shoulders, with wasting, perspiration, and malaise. In July of the same year he was seized with acute pains in the arms and legs. On arrival at Strathpeffer in August the small joints of the hands and feet were swollen, tender, and painful. He was very weak and suffered from bronchial catarrh and spasmodic cough, had a double aortic murmur, and some œdema of the legs. The urine was very acid, of specific gravity 1030, was dark with lithates, and contained a trace of albumen. In the course of two months at Strathpeffer the articular symptoms slowly abated, but mental obscuration with delusions and much restlessness supervened, showing that the joint trouble was but a part of a general breakdown profoundly affecting the nervous centres. He died in the spring of 1894, three years after the onset of arthritis.

CASE 6.—A man aged seventy-four was sent to me by Dr. Thom of Crieff. The patient was tall and athletic, and had followed for many years the profession of an engineer. With the exception that his mother had had rheumatism the family history was good. He was naturally of a very energetic temperament, and in middle life had seriously overworked himself, incurring great fatigue and mental anxiety in the management of a large navigation canal. Although often laid up for short periods from cold &c., he had never suffered much from rheumatism until at seventy-four he was seized with lumbago. Loss of flesh and progressive weakness followed, with gradual involvement of many joints, especially the small joints of the hands. A few months later he was attacked by influenza, with increased debility. On arrival at Strathpeffer in June, 1893 (eighteen months after the onset of the illness), the hands and neck presented the typical appearance of subacute arthritis, the middle phalangeal joints being enlarged, tender, and painful. The hands and front of the chest were much pigmented. There were much anæmia and dyspepsia and a suspicion of a systolic murmur at the base of the heart. [Since the above was written Dr. Thom has been good enough to give me the subsequent history. Dr. Thom says: "He died about a year ago—that is, rather more than two years after the commencement of the disease—of cardiac incompetency, mainly aortic. He got rapidly feeble for two months before his death. He continued very dyspeptic, though he was improved by Strathpeffer. The rheumatic affection of the left hand and the back of his neck was most marked. I do not think the rheumatoid arthritis presented much change during the last year of his life."]

Twelve cases in all are included in this group of senile arthritis, comprising ten men and two women aged respectively fifty-nine and sixty-seven. In considering any disorder of the senile period it is of course impossible to forget that there is another age than that of years. If it be true, as Cazalis said, "L'homme a la vie de ses artères," may we not say with equal truth, Man is as old as his nervous centres? I have placed in this group the case of a man of delicate and highly strung nervous organisation who had rheumatic fever at fifteen, but in whom there was a complete nervous and mental breakdown at forty-four, followed by severe and intractable arthritis; also another the subject of alcoholism and erysipelas, in whose case arthritis (which I would call senile) set in after rheumatic fever at forty-five. On the average of the twelve cases the age at onset is fifty-six and a half years. In respect to etiology rheumatic fever in a debilitated subject is set down as the apparent cause in two cases; influenza in two cases; nervous or mental breakdown accompanied the arthritis in four cases out of twelve, and in one or two others there was a history of nervous symptoms in former years. This is the only form of polyarticular arthritis that can be truly said, in my opinion, to belong to the degenerative period. The arthritis of the second and third decades of life, to which I find but scanty reference in the literature of the subject, belongs to the period of nervous instability. The arthritis of the climacteric epoch, or what is truly called "the change of life," is equally associated with nervous disturbance. The incidence of insanity at these two epochs affords to my mind an instructive parallel. Lastly, in the aged, or rather the senile, whether from "toil or years," there is a depressed condition of nutrition in the joints, as is shown by the frequency with which localised arthritis follows trivial injuries. And in those predisposed by family tendency to such changes, degeneration and decay in the nervous centres readily light up the sluggish fires of arthritis, to which senile dementia forms a parallel. Generalised or polyarticular rheumatoid arthritis is the clumsy name by which, as Dr. Archibald Garrod has done in his valuable book, cases such as those I have noted in this paper are at present separated from the localised arthritis commonly due to injury, which, however similar may be the anatomical lesion, runs an entirely different clinical course. Sir Dyce Duckworth has truly said, "Identity in the morbid anatomy does not imply identity in the processes leading up to it."

Having now imperfectly described several clinical varieties of this disorder, some general features remain to be noted. I should say that the 65 cases of which I have full notes were all private patients and mostly persons in comfortable circumstances. Taken altogether there are 18 men and 47 women. As respects heredity, my experience corresponds with the results quoted by Dr. Archibald Garrod. In 33 cases (just one-half) there is a family history of diseases of the joints—namely, gout 9, rheumatoid arthritis 6, rheumatic fever 5, and rheumatism 13. Considering that family history reveals too little rather than too much, may it not be considered that a positive history of hereditary joint trouble in every second case is rather strong evidence of a family arthritic diathesis? In 5 cases near relatives had died from phthisis, but as I have not been much alive to the association with tubercle I think that figure may not fully represent the connexion between the two diseases. Much has been said about the connexion between rheumatoid arthritis and rheumatism, a question which has been, as Mr. Hutchinson reminds us, made more difficult by the obscurity of the terms employed. Rheumatic fever stands apart, to my mind, as a specific infective constitutional disease, and in my own limited experience its connexion with rheumatoid arthritis is altogether exceptional and accidental. In 65 cases there are 5 in which rheumatic fever is stated to have immediately preceded the arthritis. One of these, however, was a mixed case (arthritis and osteomalacia), and 2 were in elderly and debilitated subjects, and therefore, as I have shown, not typical. Moreover, the diagnosis of rheumatic fever is not always quite clear, and rheumatoid arthritis is occasionally acute and febrile in its onset. In 4 more cases an attack of rheumatic fever preceded the arthritis by a variable interval—in one case two years only, but in this case a gonorrhœa was probably the cause of the arthritis. In the 3 others the

Digitized by Google

intervals were respectively five, twenty-five, and twenty-nine years. In respect to chronic rheumatism, the connexion with arthritis appears to me to consist in the two facts that both disorders may be set up by exposure to cold and damp, and that in both there is usually a painful enlargement of the joints. At Strathpeffer there are every year abundant examples of a painful affection of the muscles, nerves, or joints, arising from exposure to cold and damp, and particularly damp soils. It affects elderly and predisposed subjects, is essentially chronic, there is never the debility or cachexia of arthritis, and in my experience arthritis has never supervened on this form of rheumatism.

In regard to the order of onset, it appears that out of 51 cases the arthritis began in the feet in 28 and in the hands in 10. In 19 of these in which it began in the feet the disease went on by way of the hands in 13, and by way of the knees in only 6. My figures therefore support the statement that the invasion of the joints is usually centripetal, beginning from the small joints of the extremities.

With reference to mental disturbance in connexion with rheumatoid arthritis it should be mentioned that, in addition to its frequent occurrence in the senile cases, there are notes of two cases in the climacteric group in which partial and temporary insanity accompanied the arthritis. In arthritis of the young it is only exceptionally that one can learn the whole course of the malady, but three cases are known to me in this group which have a bearing on the point. In the first there was under my own observation a complete change in a cheerful person to morbid gloom. In the second case a girl developed arthritis at fifteen, suffered intense pain for seven years, and died from convulsive seizures at twenty-two. The third case is interesting from the patient's own observation of her mental state. I saw her first in 1885, and she had then suffered for eight years from the disease. She wrote me in February of the present year as follows: "To me the most trying turn the bomplaint takes is when I get in a great measure free from pain; it goes to my head, and my brain will scarcely work at all; my memory, too, gets very bad. So I may say I am always best and brightest when in pain." Dr. Ord has related a case in which mania came on when the arthritis subsided. There are, finally, two symptoms mentioned by Dr. Spender and pointing to a nervous origin of the disease. Gastric crises or unprovoked vomiting I have only exceptionally met with—in four cases only. Pigmentation in the neighbourhood of the affected joints is a much commoner observation, and one of my drawings shows a rather curious pigmentation of the nails.

It was my original intention at this point to describe briefly the localised forms of arthritis to which reference has been already made. It must suffice to say that they are, in my opinion, entirely separate from the generalised disease, and that no small confusion has arisen from confounding the two conditions under one name. I have a series of about thirty cases in which the shoulder, or hip, or knee, or one hand has been alone affected, and many in which the arthritis has been limited to the basal joint of one or both thumbs. The subjects are nearly always at or past middle age, the average age being fifty-one; and in their history, exciting causes, course, prognosis, and, above all, in the absence of constitutional symptoms, they present striking differences from arthritis in a generalised form. In the same manner I venture to separate from the latter and more serious affection numerous cases of nodi digitorum, Heberden's nodes, and lastly joint arthritis, which, in my view, are middle-age or senile changes almost always the result of hereditary gout. (See Figs. 7 to 15, which represent joint changes in advanced life.) I have already dwelt upon the fact that in rheumatoid arthritis such changes as occur in the terminal joints usually result, not in enlargement, but atrophy.

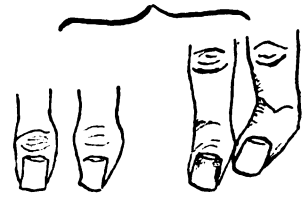

FIG. 7.

Terminal phalanges of a female about sixty years of age (gouty).

I could wish that the clinical pictures I have endeavoured to delineate were clearer and more exact in their outlines, as becomes a presentment of fact. It remains, in conclusion, to ask what inferences can be properly drawn as to the true theory and pathology of rheumatoid arthritis. In the first place the causation is evidently complex, for innumerable and diverse facts testify to an inherited local vulnerability both of the nervous centres and of the joints, and this should be placed first among the causes; next come particular conditions of disturbance incidental to different periods of life; then there is the depressing effect of antecedent illness; and, lastly, the external causes (cold, damp, and injury), which, as we know, first, and chiefly, affect the feet and hands, in which, as a rule, arthritis begins. To my mind there is strong evidence that some implication of the nervous system

takes an essential contributory part. We have gone beyond the anatomical lesion, and a disorder is found manifesting not only a general progressive affection of the joints, but other characters, to which I have referred, pointing to changes in the nervous centres. It is also found that the disorder is most frequent and most acute at the period of greatest nervous instability—namely, in young womanhood and at the climacteric epoch. In the latter case it is less severe, sometimes confined to one-half of the body and subject to intermissions analogous to the fluctuating condition of the nervous centres at that epoch; and, moreover, in senile cases it often forms a part of a general nervous and mental breakdown, and the joint changes, according to the general character of senile disease, are less marked by inflammatory reaction than in younger life. One disease of the nervous centres is known in which organs of locomotion are affected, first by a brief inflammatory condition and then by degeneration and atrophic changes; this condition in infantile paralysis is confined to the muscles. Then again in another spinal cord affection, tabes dorsalis, we have occasionally affection of isolated joints with arthritis, in which the inflammatory stage may perhaps be veiled by anæsthesia of the parts. In the present case there is a disease of the organs of locomotion in which the inflammatory period stretches over years, a disease which is frequently associated with emotional or mental disturbance and which is commonest in women, during the years when such disturbance is most common; and in this disease, according to my belief, whatever may have been its genesis in ancestral maladies—gout, rheumatism, tubercle—yet, in the individual, nervous disturbance remains the preponderating element of causation and determines in rheumatoid arthritis a condition of neurosis almost akin to insanity, but of which the principal manifestation is found in the joints.

SOME CONSIDERATIONS ON THE CHLOROFORM QUESTION, SUGGESTED BY THE REPORTS OF THE HYDERABAD AND "THE LANCET" COMMISSIONS.

BY T. LAUDER BRUNTON, M.D., F.R.S.

(*Continued from p. 23.*)

ACTION OF ANÆSTHETICS ON TISSUES GENERALLY.

ALCOHOL, ether, and chloroform are all protoplasmic poisons. If pure alcohol be poured into a cut it will irritate the sensory nerves and burn like a red-hot iron, while it will coagulate and kill the blood, muscle, or any albuminous tissues, rendering them hard and unfit for the functions of life, and it will precipitate any soluble albuminous bodies. This can be well seen by mixing a little beef juice or albuminous urine with some pure alcohol, when the whole of the albumen will be thrown down as an insoluble precipitate. What we thus see happening in a test tube has been supposed to occur also in nerve cells, and the anæsthetic action of alcohol and its congeners has been supposed to be due to their causing a condition of semi-coagulation in the nerve cells, or at any rate such a change in the substances composing them, so as to render them sluggish and incapable of performing their functions. In the mucous membrane of the mouth we may see the same action of alcohol, for a little spirit held in the mouth will soon render the mucous membrane of the cheek white by causing superficial coagulation of its albuminous constituents. We can here notice how much stronger the action of chloroform is than that of alcohol, for it not only causes much greater irritation but much more rapid and excessive whitening, and, indeed, it causes similar whitening even on the skin.

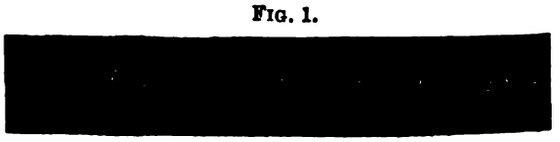
LOCAL IRRITANT ACTION OF SOME ANÆSTHETICS.

On account of their action on albuminous substances both alcohol and chloroform have a powerful local irritant action, and if held long in the mouth or applied to a piece of skin denuded of epidermis will burn almost like a red-hot iron. If alcohol be applied to the skin and its evaporation prevented by covering it with oil-silk, it will cause a feeling of burning. This is still more marked in the case of chloroform, and the burning may become so painful that it can hardly be endured. If chloroform be put on the face or its concentrated vapour be inhaled it may cause much irritation of the sensory nerves of the face, nose, and trachea, and through them affect reflexly both the heart and respiration.

ACTION ON THE NERVOUS SYSTEM.

But the vapour of all anæsthetics when inhaled in such dilution as to produce no local or reflex irritation affects the nerve centres first, and usually does so in a definite order, the highest and most complex going first and the most fundamental going last.[1] Judgment and power of thought disappear first, next sensation and voluntary motion, next reflex action, then respiration and, lastly, cardiac pulsation.

ACTION OF ANÆSTHETICS ON THE CIRCULATION.



If instead of putting liquid alcohol or chloroform into the mouth the vapour only is inhaled no pain and no whitening will be induced. We thus see that the effects of the drug upon the tissue depend very much upon its concentration. What is true of the mouth is also true of the other tissues of the body. Alcohol, ether, or chloroform will destroy any one of them if applied to tissue in a concentrated form, but when diluted will act rather as a stimulant, and will produce no marked injury. When chloroform is injected into the artery of a limb it will coagulate all the muscles and make the limb as stiff as a board; when injected into the heart, or when the heart is plunged into it, the muscular substance of the organ will be coagulated and its motion arrested, and if the heart of a frog be suspended in sufficiently concentrated chloroform vapour its movements will also cease; even nitrous oxide gas will kill the frog's heart if sufficiently concentrated.

EFFECTS OF DILUTION.

But the effect is different when chloroform is inhaled, because the respiratory centre in the medulla oblongata is more readily affected by chloroform than is the heart, and, therefore, when the blood has taken up a sufficient quantity the respiration is paralysed, while the heart continues to beat. In this respect the action of chloroform resembles that of ordinary asphyxia, whether produced by the inhalation of carbonic acid, by clogging of the bronchial tubes with mucus, by consolidation of the lungs in pneumonia, or by collapse of the lung from a penetrating wound of the chest. Both clinical experience and physiological experiment conclusively prove that chloroform, as well as alcohol, ether, nitrous oxide gas, and carbonic acid, all cause death when *gradually* inhaled by producing paralysis of the respiration, and that a period of time, longer in some cases and shorter in others, elapses between the stoppage of the respiration and the stoppage of the heart. But long before the point of danger has been reached anæsthetics—alcohol, ether, and chloroform—lower the blood pressure. This primary and constant fall depends, at least in part, on that dilatation of bloodvessels, which leads to a glow on the skin after alcohol has been taken. It is not dangerous; on the contrary, it is rather associated with the rapid circulation and consequent stimulant effect which is so well known in the case of alcohol, and, like the fall of blood pressure produced by nitrite of amyl, may be useful instead of injurious in the case of a feeble heart by lessening the resistance it has to overcome. Some very interesting observations on this subject were made by the late Dr. Anstie and recorded by him.

Dr. Anstie says:[2] "If alcohol acts as a narcotic it lowers arterial tension, increases the frequency of the pulse, and increases the dicrotism of the curve. Here, for example, is the effect of an experimental dose of half an ounce of brandy. (*Vide* Figs. 1 and 2.) A healthy young man

(*vide* Fig. 3) was experimentally intoxicated with fifty-six ounces of claret at 8 per cent. absolute alcohol (equal to four ounces and a half of absolute alcohol). The patient was in the stage of "noisy hilarity" when this tracing was obtained. The heart force was really very weak, but

FIG. 3.

the arterial tension resistance was so low that, as you see, the curve was a large one." As the primary fall of blood pressure is a constant consequence of the administration of an anæsthetic, even of alcohol, and occurs, so far as we know, in *all* cases, in those who become unconscious without a single bad symptom as well as in those who do not, we may dismiss it from consideration as a source of danger, and need not trouble ourselves much as to its cause. In all probability it is due, or chiefly due, to vaso-motor paresis, as held by the Hyderabad Commission, and proved by the experiments of Lawrie and Chamarette, of Hare and Thornton. It is probable that the fall may in some animals or some persons be aided by simultaneous weakening of the heart, as held by Gaskell and Shore. But whether this be so or not is of no practical importance in regard to death during anæsthesia, though it is of very great scientific interest. It is hardly necessary to add that this primary fall is carefully to be distinguished from that which occurs from an overdose, for if the administration of the anæsthetic be pushed too far all the functions will fail, and the heart will become feebler, the blood pressure will fall continuously, and its depression, at first slight and harmless, will finally become so great that the blood will cease to circulate and the animal will die.

ACTION OF ANÆSTHETICS ON THE PULMONARY CIRCULATION.

This subject was examined by the Glasgow Committee, consisting of McKendrick, Coats, and Newman. They found that the action of chloroform, ether, and ethidene upon the lungs consists in retardation and subsequent cessation of the circulation, first in the capillaries, then in the small arteries, and lastly in the larger vessels. The epithelial cells with their nuclei in the alveoli become invisible. The capillaries are contracted and their walls become less distinct, and the blood corpuscles present in them are partially dissolved. These phenomena are chiefly those of inflammation, due to the action of chloroform as an irritant. The consequences of arrest of the pulmonary circulation have already been considered under the head of death beginning at the lungs. When the vapour of any anæsthetic, even of chloroform, is sufficiently diluted its local action on the pulmonary circulation will be small; but if a concentrated vapour enters the lungs either from being driven in by artificial respiration or drawn in by a sudden deep inspiration it may prove a serious factor in stopping the circulation.

THE REAL DANGER FROM THE HEART.

The real danger which is dreaded, and most justly, by anæsthetists is not a mere weakening of the pulse nor even an occasional intermission, but a stoppage of the heart, which appears to be sudden and complete, which yields to no treatment, and persists in spite of all attempts to restore the cardiac pulsations. This may occur simultaneously with the failure of respiration, or may apparently precede it.

NATURE OF THIS DANGER.

The symptoms recorded are those of neuroparalysis, as given by Casper, and the question at once suggests itself, (1) Are these symptoms produced, as in Casper's cases, by suffocation; or (2) are they due to the shock of operation, or (3) are they really caused by the anæsthetic? Previous to the report of the Glasgow Committee it was generally believed that even though chloroform might weaken the heart its action was gradual, but that Committee observed in several experiments a sudden slowing or stoppage of the heart with a great consequent fall of blood pressure. These sudden, unexpected, and apparently capricious stoppages were attributed by the Committee to the action of chloroform. The cause of such stoppages was carefully examined by the Hyderabad Commission, which came to the conclusion that they were not due to the anæsthetic, but to irritation of the vagus by asphyxia. By the Glasgow Committee this action of the vagus was regarded as a source of danger; by the Hyderabad Commission, at the suggestion of Dr. Bomford, as a safeguard to the animal by preventing too much chloroform reaching the medulla. These opposite views have each experimental evidence in their support. The action of the vagus is indeed complex; it would appear that it may at one time be beneficial and at another prejudicial. It is certainly remarkable that in an animal like the rabbit, which may sometimes have difficulties in the way of breathing freely in its burrow, the vagus seems peculiarly easily irritated by stimulation of the nose or closure of the nostrils. Moreover, it is almost impossible to stop a healthy heart permanently by irritation of the vagus however strong or long continued. These facts seem to show that stimulation of the vagus is not dangerous, but rather beneficial so long as the heart is healthy. But, on the other hand, when an animal is suffocated and just about to die, the respiration and cardiac pulsations having both stopped completely, it has been found by Dastre and Morat[3] that the heart is not really paralysed, but is inhibited by the vagi, and when these nerves are cut it will again begin to beat. It would thus seem that just as the heart is failing the action of the vagus puts a final stop to it. Here the vagus seems harmful, and one would naturally think that if the division had been made earlier death might have been averted. But experiments showed that this was not so, the contrary being the case and the heart failing earlier. But whether we regard the effect of the vagus in stopping the heart as useful or prejudicial, the occurrence of such a stoppage during anæsthesia is a sign of danger because it indicates more or less interference either with the respiratory movements or the respiratory passages, a condition which, as Casper has shown, may lead either to death by asphyxia or by neuroparalysis (shock). The similarity between many cases of sudden death occurring during the administration of anæsthetics, and especially chloroform, and those of death by shock from simple strangling or throttling strongly suggests that they result from the same cause—viz., *neuroparalysis* due to interference with the respiratory passages.

ACTION OF CHLOROFORM ON THE RABBIT.

The objection is often brought against conclusions drawn from laboratory experiments on anæsthetics that the animals used were different from human beings. This is true to a certain extent, but the same objection may be made to applying to all men general conclusions drawn from any set of observations made on a certain number only of human beings. The truth is that most human beings react to chloroform in the way that dogs and monkeys do, but other people react more like rabbits. I have already mentioned that in rabbits the vagus is very easily excited, and these animals are very easily killed by chloroform. But there are two ways in which it can be used to anæsthetise rabbits with safety, and these two ways are as different as they can possibly be. The first way is to give the chloroform vapour in a very dilute state by putting the rabbit under a bell jar and allowing chloroform to diffuse very gradually into the air until the animal loses consciousness. This plan, though safe, is slow. The second plan is used for anæsthetising rabbits in the Pasteur Institute, and it seems both rapid and safe. A cloth nearly saturated with chloroform is wrapped round the rabbit's nose and head. For nearly a minute it ceases to breathe, and I believe its heart ceases to beat. Then it draws one or two long breaths and falls over at once, completely unconscious and fully anæsthetised. The way to kill a rabbit, during the attempt to anæsthetise it, is to combine careless administration with timidity, to use too strong a vapour to allow of its going off quietly—and alternately to withdraw and reapply the chloroform. The exact cause of death here I do not know, but

[3] Vide Dastre and Morat, who give the literature of the subject as well as original experiments. Archives de Physiologie Normale et Pathologique, 1884, série 3, tome lii., p. 1.

Digitized by Google

suppose it is due to the disturbance of the cardiac and circulatory apparatus by the shock of the irritant vapour at a time when the healthy balance of these mechanisms is disturbed by partial anæsthesia. The danger of such a course in anæsthetising human beings also has been pointed out by Dr. Robert Kirk, with whose practical conclusions I agree, but whose physiology I cannot understand, for he considers the cause of danger to be a backward whirl of the circulation, whereas physiologists, from the time of Harvey onwards, are accustomed to regard such a backward whirl as impossible.

WHAT HAPPENS IN A CASE OF DEATH FROM ANÆSTHETICS *per se*.

Whatever views may be held regarding the cause of *death* during anæsthesia it will be generally acknowledged that in the much more numerous class of cases of simple danger during the administration of anæsthetics the heart continues to pulsate for a varying time after the respiration has ceased. This indicates pretty plainly the broad physiological fact demonstrated by the labours of the Hyderabad Commission, and demonstrated, indeed, long before in the pages of THE LANCET by Mr. Wakley, the present senior Editor, in his younger days, that the heart centres are the most tenacious—the first to develop, the last to disappear in the human organisation. This physiological relation does not cease when an anæsthetic has been administered. In this report, under the head of "untoward" cases, those cases have been dealt with "in which more or less grave symptoms occurred, but which eventually disappeared on resuscitative measures being adopted." No less than 245 are noted in this report. The inhalers were in no way to blame, and "none were absolutely to be relied upon as a certain preventive of grave symptoms of toxæmia." The immediate symptoms in almost every case were either respiratory or circulatory, and it is to be noted that "in a very large proportion of cases the respiration failed before the heart or pulse showed signs of flagging." Likewise the measures adopted in resuscitation were in most cases those which were applicable to cases "rather of cessation of respiration than to those of cardiac failure." Pp. 1112–18 contain some interesting records. What usually happens is this. The respiration gradually fails, and when the administrator, whose attention, perhaps, has been otherwise engaged, comes to notice the respiratory movements he finds that they have ceased; but the heart is still beating, and usually, though not always, artificial respiration suffices to bring the patient round. This is the kind of death which chloroform pure and simple causes either in man or in animals. It is the kind of death which has been observed by the Committee of the Royal Medical and Chirurgical Society, by the Hyderabad Commission, and by almost all other physiological experimenters; but this is not the kind of death which is so much feared by anæsthetists. What they dread is the sudden cessation of pulse and respiration together or the stoppage of the heart before the respiration. This sudden death may occur almost as soon as the administration of the anæsthetic has begun, and long before the patient is under its influence; it may occur at a later period after a violent fit of struggling, and sometimes appears to come on just after a fresh quantity of chloroform has been poured on to the inhaling apparatus and a more concentrated vapour thus administered; it comes on sometimes at a late period in the operation, without any cause that can be definitely assigned; it comes on also just when the operation is finished and the patient is beginning to come out of the state of anæsthesia—the state at which vomiting is usually to be expected. The cases of simultaneous failure of heart and respiration are so comparatively few that other factors besides the mere anæsthetic may be looked for to account for the occurrence in such cases. The tables contained in the report give only fifty-eight such cases out of a list of 506 records. Further, many of these cases appear to indicate that very accurate methods of clinical observation have not at all times been employed in obtaining the records which are summarised in tabular form on p. 633 of the report.

SUMMARY OF EXPERIMENTAL EVIDENCE.

The tripod of life consists of the heart, the lungs, and the brain. The immediate cause of death consists either in failure of the heart (syncope) or of the lungs (asphyxia). The brain may cause either (1) heart or (2) lungs to fail separately, leading to (1) syncope or shock, or to (2) coma and subsequent asphyxia. The brain may (3) cause the heart and lungs to fail together (neuroparalysis). These modes of death are distinguished by their symptoms and post-mortem appearances. The symptoms of rapid asphyxia from stoppage of the respiration are nearly the same as those from sudden stoppage of the heart, because they are due in both cases to the respiratory centre in the medulla oblongata being deprived of arterial blood. In the first case—viz, failure of the respiration—this occurs because there is no arterial blood in the body at all, the whole blood in the body having become venous, and in the second, because the blood becomes venous in the medulla itself when it stagnates from stoppage of the heart, although that in the aorta may still be arterial. These symptoms are—(*a*) increased respiration becoming more and more violent and ending with (*b*) convulsions if the brain be not dulled. If the brain be dull either from the effects of accumulating carbonic acid, as in ordinary coma, or from the effects of a narcotic or anæsthetic, the respirations gradually become weaker and finally cease. Sudden and violent gasps just before death usually indicate stoppage of the heart and consequent irritation of the respiratory centre by stagnation of blood in it before it has lost its functional activity. In slow failure of the heart the face is likely to be pale, and in slow failure of the respiration blue or livid; but, as Casper remarks, in rapid failure of the respiration there may be nothing distinctive in the appearance. In death from neuroparalysis there is simple stoppage of every function at once. In asphyxia the right side of the heart and lungs are engorged, and the left heart nearly or quite empty. In death from syncope in neuroparalysis the right heart and lungs are not engorged and both sides of the heart contain no blood or only a little. All experimental evidence goes to show that anæsthetics, when given without interference with the respiration, dull the brain and never kill by neuroparalysis, but cause death by gradual failure of the respiration, the heart continuing to beat for some time after the breathing has stopped. Death by neuroparalysis is an exceedingly common result of interference with the respiration in cases where no anæsthetic has been given. It is therefore probable that when death occurs from neuroparalysis during the administration of an anæsthetic, it is not due to the anæsthetic *per se*, but to some other cause, such as interference with the respiration by chloroform containing irritant substances, or even too concentrated vapour of pure chloroform, by too close application of the inhaler, by interference with the respiration in some other way, or by the "shock" of an operation.

CLINICAL EVIDENCE.

SUDDEN DEATH.

1. "*Shock*."

The causes of sudden death, apart from anæsthetics altogether, are very imperfectly known. Sometimes a patient suffering from heart disease, and especially from fatty heart or aortic regurgitation, suddenly falls down dead. Most people are contented to say that the occurrence is due to failure of the heart, but they do not know the exact mechanism, nor do they know at all fully the mode in which death occurs from what is termed "shock." Death from shock was a frequent occurrence before the introduction of anæsthetics, and we are sometimes apt to forget that it may still occur, although anæsthetics have been administered. In the tables on p. 632 of THE LANCET report this is borne out, for it appears that Dr. Snow records forty-nine cases of deaths during the administration of chloroform as due, or probably due, to shock. From Hospital Records,[4] p. 633, sixteen such deaths are recorded as attributable to shock from some cause or other. The report states on p. 761 that "many instances occurred in which whilst comparatively trifling operations were being performed a fatal accident occurred." On p. 631 THE LANCET Commissioner continues: "In some cases the causes alleged do not appear to correspond with the symptoms given. Thus one death is described as due to 'syncope,' although it is stated that 'food was found in the

[4] THE LANCET, March 13th, 1893.

Digitized by Google

windpipe.'" There are numerous records of this kind. Again, on p. 634 cases are recorded "as having been due to syncope when from the symptoms and phenomena of narcotism described there was a strong presumption that the death was due to asphyxia." How far, therefore, the 154 cases recorded under the heading of "Syncope" may be due to shock originally it is hardly possible to estimate.

2. *Paralysis of the Nerves and Heart.*

The following cases are put down as paralysis of the heart or nerve centres, which implies the neuroparalysis which Casper defines as synonymous with shock. They are given here for reference—namely, Cases 130, 157, 163, 199, 204, 205, 225, 261, 269, 275, 343, 419, 437, 461, 513, 547, and 594. The terms used for describing these deaths—"shock," "paralysis of the heart," "syncope"—practically mean the same thing. Distinction may be made between them when the patient is awake; but when under the action of anæsthetics it is for practical purposes impossible to do this. In a great number of the cases enumerated above it is quite clear that the respiration began to show signs of disturbance before the heart failed, and had proper attention been paid at once to the symptoms of alteration in this respect it is quite possible that the fatal results might have been averted. Notwithstanding this the cases have been reported as those in which the pulse and respiration have failed simultaneously. In several cases the operation was such as necessitated the patient being turned over, so that while performing this movement the respiration might be partially impeded by the position, and, at any rate, the manner in which the respiration was being carried on would not be so evident to the anæsthetist as with the patient in the supine position. Again, the operation, it will be observed, was in many cases performed upon the face, and naturally the administration of anæsthetics for such operations is more difficult than usual. The respiration might in such cases easily have been interfered with without being at once obvious to the administrator. Taking all this into consideration, it is most probable, from a perusal of those cases in which the pulse and respiration are recorded as failing together under chloroform, that some are erroneously so stated. Still is there a sufficient number of authentic cases recorded to support the general proposition that the simultaneous failure of the pulse and respiration does occur during the administration of chloroform. This symptom is one which indicates death from shock or neuroparalysis.

CLASSIFICATION OF CONTINGENCIES.

Various accidents may arise from the use of an anæsthetic. These may be due either to the anæsthetic itself or to the operation occurring during the administration of the anæsthetic. Deaths may occur in the first stage before anæsthesia has been effected and before any operation whatever has been begun. We may find deaths occurring during the stage of excitement which succeeds the first administration of an anæsthetic, or we may find them occurring during the stage of complete anæsthesia during recovery from the anæsthetic. To these deaths may lastly be added another class, those which occur two or three days after the anæsthetic has been administered. These usually take place in cases where the anæsthesia has been kept up for a considerable length of time, and are said by some to be due to changes in the heart and kidneys produced by the anæsthetic—a sort of secondary death. A study of the cases catalogued will bear out this classifications, which differs in some respects from Snow's.[5]

GROUP I. DEATHS ARISING BEFORE ANÆSTHESIA HAS BEEN EFFECTED.

It is important to bear in mind not only that anæsthetics in general may produce death from failure of the respiration, but that chloroform especially tends to aid the toxic action of venous blood upon the heart, so that an animal that has received chloroform dies much more quickly from chloroform *plus* venous blood than from venous blood alone. The death which asphyxia alone would cause is quickened by the administration of chloroform, whereas anæsthetics containing no halogen do not seem to have such an action to any great extent.

In the first stage of the administration of anæsthetics we occasionally find a patient dying at once before the operation has been begun. The following cases illustrate this point:—

No. (Series A.)	Notes.
23.	Patient died at once.
28.	Died "after four or five inspirations."
(Series B.)	
9.	Had scarcely made four inspirations.
32.	Died in an instant; removal of small tumour of gum.
34.	Died instantly.
63.	Pulse and respiration ceased at same moment.
64.	In a moment the patient was dead.
95.	After three or four inspirations respiration ceased.
104.	Patient died instantly without warning.
116.	Pulse stopped suddenly.
122.	Pulse failed and patient died immediately.
126.	Suddenly became rigid and pulse stopped.
153.	Died suddenly.
158.	Respiration ceased; died suddenly.
187.	Pulse and breathing suddenly ceased.
253.	" " " " " Scrofulous tumour of jaw (which jaw not stated).
275.	Pulse ceased; died instantly.

The symptoms in these cases are those of neuroparalysis, and in all probability may be rightly attributed to interference with the respiratory passages, such as sudden reflex closure of the glottis, having a result exactly like that of throttling.

The following cases have a bearing on this point, Nos. 5, 8, 10, 16, 22, 28, 30, and especially 54 of this group. A similar result would in all probability have ensued if, instead of putting a handkerchief with chloroform upon it before the patient's nose, a dry handkerchief had been simply pressed over the face so as to obstruct the breathing, or if the patient had been strangled by a cord round the neck. The same accident has often happened when pure nitrogen or hydrogen has been inhaled. But some deaths may be due to another cause—namely, mental impressions, which may arise either from the simple thoughts of the patient, sometimes, perhaps, aided by the smell of the anæsthetics, or even from simple irritation of the skin by a slight operation. As showing that mere mental impression will cause death, there is an instance recorded in which the physician felt afraid to give an anæsthetic to the patient, and the patient felt afraid to take it. In order to give a semblance of an anæsthetic, and if possible lessen the pain by suggestion, the physician placed a cloth over the patient's nose as if he were going to administer an anæsthetic, but poured upon it nothing whatever, yet the patient died from sheer fright. This condition finds further illustration in Case 517, on p. 914, with the accompanying footnote referring to the *British Medical Journal* case, Oct. 5th, 1889, page 778, where a case is recorded of a female insisting on taking chloroform for extracting teeth. "The dentist, pretending to comply with her wish, gave her eau-de-Cologne." After two or three inspirations she fell from the chair and died. We find also similar cases occurring where the patient has died immediately after a little chloroform has been given and the operation has just begun—the first stroke of the knife has killed the patient. But patients have died from the shock of very trivial operations without the administration of any anæsthetic whatever, and Sir James Young Simpson has recorded the case of a man who died simply from the slight incision necessary to open a boil. The cause of death in this case was "shock." The nature of shock, as I have already pointed out, is a very complex thing. At one time I was disposed to regard it as due to some sudden change in the distribution of blood, probably either from stoppage in the heart, dilation of the arterioles, or paralysis of the veins, so that the blood, instead of coursing through the arterial system, became accumulated in the venous system. There is one experiment, however, that shows that shock is due in a great measure to an influence upon the nervous system apart from the circulation. When a frog is decapitated it falls at once into a condition of shock apparently due to the action of the operation on the whole nervous system, and it does so whether the circulation be free or whether the heart be ligatured and the circulation stopped, although recovery occurs much more rapidly when the circulation is strong. Shock may be to a certain extent induced by mental impression, as was noticed long before the introduction of anæsthetics. In

[5] It is to be borne in mind that the causes of death are those assigned by the original reporters of the cases and not by the Commissioners of THE LANCET.

Digitized by Google

his book on "Gunshot Wounds" Guthrie tells us that when butchers were ordered to be bled they almost invariably fainted, whereas other people did not faint. The butchers apparently fainted almost at the first sight of blood, and Guthrie's explanation is that in the minds of butchers, who are engaged constantly in killing animals, the shedding of blood is connected inevitably with the occurrence of death. In the animals they slaughter death happens on all occasions, and the connexion was established in their minds so firmly that they thought whenever they saw the blood death was inevitable, and they fainted from psychical excitement.

SYME'S REASONS ADDUCED.

Professor Syme used to say that he had never seen in the Infirmary of Edinburgh a single case of death from chloroform. Now this was a great admission, especially by Professor Syme, because chloroform was introduced by his great opponent Sir J. Y. Simpson, and if any flaw had existed in his rival's statements Syme would have been sure to point it out. "The reasons for this," he said, "are twofold. First of all, we always use the best chloroform, and, secondly, we always give plenty of it." Now the second part of his advice was very forcibly illustrated when I was a student. A young lady was going to have her teeth put in perfect order by the dentist just before her marriage. A surgeon gave her chloroform. The young lady was well known in society, and the fact of her marriage was known very widely, and one may be quite sure that the chloroform was administered with the greatest possible care. She died while the tooth was being extracted. It is unlikely that the surgeon gave too much upon that occasion. Ten days afterwards this same surgeon gave chloroform a second time for a similar operation, and it is quite certain that if he had given too much on the first occasion he did not give it in too large quantities the second time, but the second patient died also. The reason why these patients died was almost certainly that they got too little chloroform. If it had only been pushed a little further so as to prevent shock in all probability they would have recovered.

As with alcohol, so with anæsthetics—one must push the anæsthetics so far as to paralyse the reflex nerve centres, through which shock is likely to occur. These then are some of the precautions to be used at the beginning.

EFFECT OF POSITION.

But shock is likely to occur much more readily according to the position which the patient is occupying. Cases bearing on position as a factor may be found on p. 1114; Nos. 20, 21, and 38 may be carefully noted; also on pp. 704 (No. 44) and 767 (Nos. 170, 771, 228, and 229). A mixture of chloroform and ether has been used in Case 8 (page 1487) for division of the hamstrings. The death is put down to "shock" rather than to the anæsthesia. When a man is in the upright posture bleeding tells much more quickly upon him than if lying down. A much greater quantity of blood can be withdrawn without the patient fainting when he is in the recumbent position, and when fainting does occur, from whatever cause, one of the first things usually done is to lower the head or even to put the patient in a sloping position, with the head at a lower level than the limbs, so as to make the blood flow towards the head. The patients should therefore always be, if possible, lying down or more or less recumbent, but never upright, when chloroform is being administered. It is in the dentist's chair that the greatest risks from anæsthetics occur.[6]

HOW TO COMBAT PSYCHICAL EXCITEMENT.

Psychical excitement ought to be combated as far as possible by an assurance to the patient that there is no danger, and also by allowing the anæsthetic to be very gently inhaled at first, so as not to cause any fear. If a cloth dipped in chloroform or a mask containing a quantity of ether be held before the patient's nose the psychical excitement is increased, and actual embarrassment of the respiration may thus be induced. In administering anæsthetics it is advisable to give the anæsthetic gently, so as to avoid exciting the patient's mental condition, and also to avoid irritating the upper nasal passages.

HOW IS SHOCK TO BE AVOIDED?

The question now arises: How is neuroparalysis or shock to be avoided in the first stage of anæsthesia? First of all it is clear that the towel or inhaler used should not be too closely applied at first to the patient's nose and mouth, so as to cause choking. It is well known that as patients become insensible they are able to inhale a stronger vapour without apparent disturbance than they can do at first. My late colleague, Dr. Patrick Black, in an admirable essay on chloroform, quotes a case in which two patients in good health had chloroform administered. The first one passed quietly into the anæsthetic condition; the second became excited and struggled, the arms became rigid, the face congested, and the respiration suspended by spasmodic fixture of the chest. The reason of this difference was that the chloroform was well diluted at first and the vapour strengthened afterwards. In the second the strong vapour was used at the beginning, the valve not having been altered after the first patient had been removed.

IRRITATION OF THE RESPIRATORY PASSAGES.

Care ought to be taken that only pure chloroform, free from any irritating products, is used, because decomposition products may cause by themselves spasm of the glottis apart from anything else. Deaths from this occurrence are not due, in the strict sense of the word, to the effect of the anæsthetic upon the system generally, but in all probability are caused by local irritation in the respiratory passages. This irritation is not necessarily connected with chloroform anæsthesia, but is due either to an impure preparation of it or to its faulty administration.

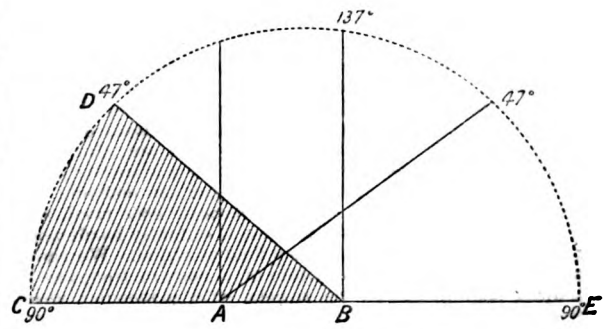
SPASM OF THE GLOTTIS AS A CAUSE OF DEATH.

I once had a curious experience. I was in a swimming bath, luckily for me only in about three feet of water. A drop of water got up my nostril, and at once intense spasm of the glottis came on. The chest was completely empty of air; and, although I put my hands upon my hips so as to get a purchase for the auxiliary muscles of respiration, it was only after a considerable space of time had elapsed that the spasm relaxed a little and some air entered the lungs. In this case a single drop of water getting into the nose produced this reflex spasm. A somewhat similar spasm may be produced by inhaling very strong liquor ammoniæ, but it is not so violent. Now, this kind of spasm is not at all uncommon during the administration of anæsthetics, and its existence is shown by a particular kind of stridor evidenced in the breathing. It is somewhat like the stridor of croup, or laryngismus stridulus, sometimes termed a "crowing inspiration," so that one of the risks here is danger from asphyxia due to the contraction of the vocal cords by spasm. Now, in my own case in the swimming bath, although at one time I seemed to be very near death, I came round very rapidly. If I had been in deep water I should have been drowned, and if I had been under the influence of anæsthetics I might not have come round; for they have the power of depressing the respiratory centre to a great extent, and at the same time of interfering to a certain extent with the heart as already described. An interesting case in this connexion is No. 19 on p. 1114. Another form of this kind of death is that recorded on p. 694, Case 4, in which the patient said "I choke," and immediately died. A second experience I have had may also be interesting as possibly throwing some light upon deaths which occur during recovery from chloroform anæsthesia, where the patient has had slight symptoms of vomiting, but where the glottis has not been mechanically obstructed by vomited matters. One day when walking sharply immediately after breakfast a little food regurgitated into my mouth. It seemed in some way to have caused reflex spasm of the glottis because, although no coughing occurred, I immediately became almost asphyxiated, unable to walk, and had the utmost difficulty in getting air into the chest. Spasm of the glottis such as occurred from this slight regurgitation might very possibly have proved fatal during an operation. The tendency towards this effect, which is developed in chloroform after prolonged keeping, has been demonstrated over and over again. Pure chloroform is very slightly irritant as compared with chloroform containing chlorinated compounds, and it is evident that freedom from such contaminations is an important element in the safe administration of chloroform. But the preceding report shows that it is not sufficient always to rely upon the purity of the chloroform as originally made, because if the bottle has been exposed to light, and possibly quantities taken out of it and poured back again several times, the chloroform is almost certain to undergo an amount

[6] The effect of posture on the blood pressure was shown by the Hyderabad Commission in Experiments 31, 32, 33, 40, 79, 81, 83, 104, and 106.

Digitized by Google

of decomposition and become irritating. To avoid this Professor Ramsay of University College has suggested that it should always be freshly distilled from caustic lime, but this precaution can only be employed in large hospitals, nor, indeed, is it usually required if a pure chloroform be got at the first and kept in a cool dark place in well-stoppered bottles, which should be small, so that the quantity they contain should not be long in being used up after the bottle has once been opened.



(To be continued.)

ON THE DISADVANTAGES OF MONOCULAR VISION.

BY SURGEON-MAJOR H. R. WHITEHEAD, F.R.C.S. ENG.,
ASSISTANT PROFESSOR OF MILITARY SURGERY, ARMY MEDICAL SCHOOL.

ALTHOUGH this subject has a very particular military application, at the same time few subjects possess a more important and practical interest from a public point of view. At the first glance it may seem somewhat unnecessary to lay great stress on the possession of binocular vision, provided that the vision of the sound eye is good; but when we fully inquire into the subject we shall appreciate the difference which really exists between binocular and monocular vision, and wherein lie the essential differences which separate the one from the other. Monocular vision imposes serious disadvantages on men who are following, or are anxious to follow, certain special occupations which demand for their proper performance a high degree of visual efficiency. We may be sure that nature has provided us with two eyes for a very good reason, and not merely reduplicated the organ in case of the loss or injury of one member, although this, no doubt, is a very wise provision. From our knowledge of the intricate arrangement of the fibres of the optic nerve and optic commissure without the eye, and the expansion of the optic nerve into the retina within the eye, it is evident that a very elaborate arrangement exists for the proper performance of binocular vision. Physiologically we know how perfect this system is and what comparatively slight causes may disarrange it. Evidently great loss of function must result from the absence or impairment of the sight of one eye. The tendency of the age is, and rightly so, to demand an increase in the severity of the tests for eyesight in those avocations in which a certain standard of acuteness of vision is considered necessary, and a more stringent application of the tests which actually exist; and not to regard this part as the least important of the physical examination of a candidate, and therefore to be conducted in a haphazard and perfunctory manner. It becomes more and more evident, not only to the medical profession, but also to the general public, that many distressing disasters which shock us from time to time—such, for instance, as railway collisions, collisions at sea, &c.—appear as if they must have been produced by the inability of some individual to recognise a signal, the colour of a lamp, or the relative position and distance of vessels. The conflicting and unsatisfactory evidence which too often follows at the subsequent inquiry into the causes of such accidents frequently appears to point to this solution as the only feasible explanation. The case is still further, unfortunately, liable to be left in doubt by the loss of the individual primarily responsible for the accident, and the inability, therefore, to completely clear up the case by physical examination. The obvious duty of medical men entrusted with the application of the tests for visual acuteness is not only to know how to apply the tests, but also the exact qualities of the vision required, and to thoroughly comprehend what constitutes reliable vision in the case of men who are to be entrusted with responsible positions where good sight is a necessity. In studying the phenomenona of binocular vision we are aware that when each eye is directed towards an object the eyes are slightly turned inwards, so that the central rays from the object fall on the yellow spot of each eye; if this were not so diplopia would result. If the object is solid certain parts of the image are focused on corresponding parts of each retina. Images of certain other parts of the object are formed in each eye singly. The result is, however, that a combined impression of the object is presented to the brain. It follows from the mental impression produced that binocular vision gives information on three heads—namely, the length, breadth, and depth or thickness of the object observed. The relative position of a series of objects situated at different distances from each other will also be discerned. Now, if one eye alone is used we shall find that only the length and breadth of the object are discerned, and that the third factor—viz., depth or thickness—is wanting. The power also of distinguishing the relation of the various objects in the landscape is also in a large measure lost. A series of objects at various distances from each other will consequently appear as if they were on the same plane, and will resemble in this respect a photographic picture. These defects of monocular vision can be remedied to a certain extent by intelligence, practice, and experience.

The fact that the acuteness of vision is duller in monocular than in binocular vision is also well established. The alertness or quickness of vision is also sensibly diminished. Another immense disadvantage of monocular vision is the contraction of the field of vision which this necessarily implies. In experimenting with the perimeter on the field of fixation it will be found that the prominence of the nose absolutely limits the field of fixation on the inner side, and therefore the field does not reach in this direction a greater extent than about 45°. If the field of fixation be taken for each eye separately, it will be found that about from 10° to 15° are added when both eyes are used. Perhaps, however, the contraction of the field of vision is more clearly shown when the field of indirect vision is taken for each eye separately in the horizontal plane, and the two charts are shown together as in the accompanying diagram. It will be found

that each eye is capable of about 90° of peripheral or indirect vision in the horizontal plane on the outer side, and about 47° in the same plane on the inner side. If both eyes were used the indirect vision would be equal to about 180°. One eye acting alone is capable of about 137°, and therefore the actual amount of the field of vision lost when one eye alone is capable of seeing is about 43°. This is shown in the diagram by the shaded part.

I have mentioned that the alertness of vision is less in monocular vision. We must also bear in mind that the alertness of vision for colours is also sensibly diminished in monocular vision. The brightness and saturation of the colour appear less than when both eyes are used. It will be apparent from what I have already said that certain disadvantages result from monocular vision. These may be summarised as follows: (1) loss of power to interpret the relative position of objects; (2) contraction of the field of vision; (3) decrease of acuteness of vision; (4) decrease of alertness of vision; and (5) diminution of alertness for colour vision. To these I may add two purely military objections—viz.: (6) difficulty in firing from the left shoulder, as proposed in cases where the right eye has been lost or damaged; and (7) liability to catarrh of the socket when an eye has been enucleated. I will now examine a little more closely into each of these disadvantages and try to assess the actual amount of disability they impose.

1. *Loss of power to interpret the relative position of objects.*—It will at once occur to us that there are some special occupations in which it is absolutely necessary that this power should be present. The impairment of it, from a military point of view, would lead to great loss of efficiency. In the first place a soldier, to be a good marksman—which, after all, is one, if not the most important, of his qualifications—must be able to judge the distance of the mark at which he wishes to fire. In practice this is very often a fixed distance, and he knows without any effort of judgment to

Digitized by Google

what distance to sight his rifle. If, however, he be afflicted with monocular vision and has to judge the distance, as he has to do in certain exercises in peace and nearly always in actual warfare, he will find very great difficulty. A soldier judge the distance of an object a good deal by its relative size and relation to other objects. If he were the subject of monocular vision and the object were moving and altering its relative position to other fixed landmarks quickly, he would not be able to estimate with sufficient rapidity the distance for which to sight his rifle. Many minor defects would also come to light on parade, and his inability to properly appreciate distance would tell greatly against him. In seafaring life the dangers arising from this cause would be very marked. In a crowded water the safety of the ship depends on the officer in charge fully appreciating the relative position of his ship to others, and he instinctively relies on this power to tell him if he has room and time for certain evolutions. We can imagine no more serious defect for a seaman than the loss of this sense. Although its absence would be most detrimental in the case of the ships' officers, yet in a certain degree its loss would act prejudicially in the case of the men.

2. *Contraction of the field of vision.*—We have only to consider the question for a minute to be convinced of the vital objections that exist to placing reliance on the possessors of monocular vision in those positions where a high standard of vision is requisite. I have previously stated the amount of the contraction in the horizontal plane, and the exact loss not only that the direct but also that the indirect vision sustains in substituting monocular for binocular vision. I take as an example an incident in military life. Let us imagine the position of a sentry in a hostile country where a war is being waged against savage tribes. The whole attention of a man employed on such a duty should be directed to detect the slightest movement near his post, and by a timely appreciation of danger to prepare his comrades for attack. The experience gained from the history of our campaigns will probably suggest not a few instances where, in spite of the most close and attentive watch, especially in savage warfare, the enemy have been able to steal up to the position and deliver a most unexpected assault. If such instances are common with men of presumably full visual acuteness, how much more likely are they to occur when a man is seriously handicapped by the loss of part of his normal field of vision. We should be very wrong to trust the safety of a body of troops to the limited field possessed by a man with monocular vision. Supposing his attention to be directed to some object in front of his post, some 40° in the arc of normal vision would be entirely lost to him, and he would be absolutely blind to this extent. The same remarks would hold good as regards the sailor. The man on the look-out, on whose vision the life of the entire ship's company might depend, would be to all practical purposes blind to the extent mentioned when his direct vision was occupied by objects in front, and it is at once recognised how serious this loss of function would become under these circumstances. Even the best shipping companies are not as particular, perhaps, as they might be with regard to the acuteness of vision of their sailors, and it is impossible not to have an uneasy feeling when thinking, if this is so with the best, what must be the condition of the vision of some of those employed on the inferior lines.

3. *Decrease of acuteness of vision.*—I have previously stated that it is an undoubted fact that monocular vision is not so acute as binocular vision; the tests for eyesight as a rule admit of such a low degree of acuteness that we cannot afford to allow a still further reduction of this by substituting monocular for binocular vision. What, perhaps, is more important, however, is the loss of alertness of vision.

4. *Decrease of alertness of vision.*—This function is quite different from the mere acuteness of vision and deserves a greater measure of attention than is usually paid to it. It is the power to recognise with celerity objects presented in the visual field. The power to do this can be very greatly increased by practice. Soldiers and sailors should be trained in this respect. As an example of how much may be done in this way I may instance the rapidity with which signallers can with practice communicate by either flags, heliographs, or lamps. From a military aspect it is of the first importance that men who may be employed as sentries or vedettes should have this faculty fully developed. The gleam of a spearhead or the raising of a head for a moment over the brow of a neighbouring hill may be all the warning a sentry may receive of the presence of foes near at hand, and the ability to receive and distinguish aright such impressions may be of incalculable benefit to the force to which the man belongs. An engine-driver running at a high rate of speed has only a momentary glance at his signal, and this often in such states of the atmosphere as to interfere seriously with the normal acuteness and alertness of vision; if he fails to interpret correctly the signal the result may be a great disaster. This power is not less important to the sailor, who may be able by its aid in thick weather to catch a perhaps instantaneous view of a light, landmark, or neighbouring ship.

5. *Diminution of alertness for colour vision.*—This very important factor is liable to be overlooked in estimating the disadvantages of monocular vision. Many people who would not be described as colour-blind still have some confusion in detecting colours, and depend a good deal for their appreciation of the shade on the amount of luminosity. Any physical condition which diminishes the acuteness and alertness of colour vision must be regarded with concern, as any circumstance which would hinder the immediate recognition of a coloured lamp or signal, or cause any confusion in doing so, might lead to very serious results. The engine-driver, the ship's officer on watch, or the seaman on the look-out must be able, for the safety of the charge confided to him, to recognise, even under unfavourable conditions of the atmosphere, without any hesitation whether a given signal or light is red or green. When we consider the rate at which an express train may be running, the possibility of the light being hidden until close to a curve, and the varying states of atmosphere and illumination we shall understand the value of the alertness of colour vision. The question of the quantitative determination of colour vision is still in its infancy, and but little attention has been paid to it. The ingenious apparatus devised by Mr. Brudenell Carter and described by him in THE LANCET[1] is, however, a step in the right direction and affords the means to record accurately, if desired, the exact acuteness of colour vision. I shall not do more than draw attention to the two distinctly military disadvantages, explaining shortly the reasons for such.

6. *Difficulty in firing from the left shoulder if the right eye has been lost or damaged.*—The handle of the bolt projects from the right side of the new (Lee-Metford) rifle. In firing from the left shoulder, which, if the right eye is damaged, is the proper position, the bolt of the rifle is apt to catch against the belt and accoutrement on the left side of the soldier.

7. *Liability to catarrh of the socket if an eye has been enucleated.*—Under no circumstances would it be advisable to pass a man fit for active service if the eye has been removed. The dust, smoke, and dirt inseparable to a campaign would almost assuredly set up a catarrhal condition of the socket. Apart from all other considerations this would disqualify him.

I have hitherto limited my remarks to monocular vision due to the complete loss of the sight of one eye. I must not, however, fail to recognise the fact that many of the dangers attendant on monocular vision may be established in those cases in which the sight of one eye is normal or nearly so, while the sight of the other eye is bad. Although the effects of such are not so pronounced, perhaps they are not less serious. In such cases the better eye does practically all the work, and unless the loss of vision in the other eye is simply due to an error of refraction, which can be fully corrected, to all intents and purposes the person is devoid of binocular vision. It is therefore absolutely necessary in formulating tests for visual efficiency that the sight of both eyes should be tested separately and a limit placed on the loss of acuteness of each eye. The test, for instance, for candidates for commissions in Her Majesty's army is that the candidate shall read at least $\frac{6}{36}$ with each eye separately, and that the loss of acuteness, if present, shall be due only to an error of refraction and be capable of correction by lenses to $\frac{6}{6}$ in one eye and $\frac{6}{12}$ in the other eye, thus allowing only a small difference in the acuteness of vision between the eyes after lens correction. Dissatisfaction is often expressed that, although a candidate may be emmetropic in one eye, yet if he fails to see $\frac{6}{36}$ with the other eye he is rejected. From the foregoing remarks it is seen why it is so desirable that a limit should be placed on the deficiency of sight of the worse eye. For the same reason strabismus is a condition which debars from military service, and should also cause disqualification in any occupation where a high degree of visual efficiency is required. Here, again, the field of vision may be seriously

[1] THE LANCET, March 17th, 1894.

Digitized by Google

interfered with, and, apart from the significance of strabismus in other ways, rejection on this ground alone is sufficient.

I have said enough, probably, in the narrow limits of the present article to demonstrate clearly the chief disadvantages of monocular vision. I might enter much more into detail and point out further the many occupations in which monocular vision is distinctly objectionable; their own experience will suggest many such instances to the readers. It is perhaps questionable if the full value of periscopic vision is sufficiently understood, and the amount of loss of function which any interference with it causes. As a practical suggestion in connexion with my remarks I wish strongly to urge the importance of a more thorough and systematic examination into the eyesight of the employés of railway companies and of the mercantile marine service. Much has, I know, been done in this way of late years, but much is still required to give greater security to the travelling public. The very great danger, especially in the case of the mercantile marine, of an inefficient examination should be recognised, and the Board of Trade pressed to place such restrictions as would prevent not only the officers but also the men afflicted with indifferent vision of one or both eyes from serving. Men who are employed in such pursuits should not only be tested on first appointment, but should also be subjected to re-examination at stated intervals. These examinations should be carried out by independent examiners specially appointed to these positions, and who thoroughly understand not only the application of the tests, but also the reason for imposing them, and the quality of vision they demand.

TWO CASES OF SEVERE TRIGEMINAL NEURALGIA DUE TO NASAL DISEASE.

BY M. P. MAYO COLLIER M.S. LOND., F.R.C.S. ENG.,
VICE-PRESIDENT OF THE BRITISH LARYNGOLOGICAL AND RHINOLOGICAL ASSOCIATION.

OF the numberless cases of "tic" recorded in the various journals and other publications an extremely small proportion have been attributed to nasal disease. In an immense majority of the recorded cases the nose has apparently never been examined at all, and this in face of the fact that there exists a ganglion called the spheno-maxillary or nose ganglion, and that this ganglion is closely associated with the main trunk of the second division of the fifth nerve, and distributes branches to almost the whole of the interior of the nose and naso-pharynx. Granted that a very large number of these cases of trigeminal neuralgia are due to peripheral irritation, common sense would suggest an examination of such an extensive surface of peripheral distribution as the interior of the nasal cavities. In the two cases I am about to relate the nose was never examined until I was consulted, and in the first case a distinguished surgeon had counselled the serious procedure of the removal of the infra-orbital nerve without looking into the patient's nose. To be brief, in the early part of last summer my colleague, Dr. Cagney, requested me to see a poor woman who was a martyr to facial neuralgia of a severe type and of some twelve years' duration, with a view to the examination of her nose. Even a breath of air, or, indeed, the slightest contact with lips, tongue, or face, would precipitate an attack of agonising pain, the patient moaning and grinding her teeth with the severity of the paroxysms. The removal of teeth and the exhibition of medicines and galvanism failing, an operation on the infra-orbital nerve was about to be performed just previous to my being consulted. My examination revealed extensive disease of the middle turbinated bone on the same side as the neuralgia. I sat down there and then in the presence of Dr. Cagney and removed with the cold snare the greater portion of the diseased structures. From that day and hour the neuralgia practically ceased, and, with the exception of a few slight relapses due to the accidents incidental to the healing process in the nose, the woman was and still is completely relieved of her misery. A short time after this another colleague, Dr. Leonard Guthrie, hearing of this woman's case and having under his care, in concert with Dr. Turner of the Regent's-park Hospital, a severe and intractable case of trigeminal neuralgia, kindly suggested that I would take the case in hand also and see what I could make out of it. Curiously, this was a repetition of the last case. The nose had not been examined. The disease had lasted four years and the attacks were becoming more frequent and more severe. In this case a marked deflection of the nasal septum would have baulked any but a skilled observer, but the probe told a tale of diseased middle turbinated bone with numerous polypi. These were at once removed, and but for one or two occasional twinges the neuralgia has disappeared, apparently never to return again. Both these cases were residents in the wards of the North-West London Hospital, and have been exhibited cured, after some months, before the British Laryngological Society, the North-West London Clinical and other societies.

Harley-street, W.

NOTES OF A CASE OF CONCEALED ACCIDENTAL HÆMORRHAGE.

BY WILLIAM BLIGH, M.D. LOND.,
LATE HOUSE SURGEON AND OBSTETRIC RESIDENT, GUY'S HOSPITAL.

ON Dec. 2nd, 1894, I was called at 4 P.M. to see a woman aged forty-three, the wife of a labourer, who gave the following history. She had had ten children and two miscarriages; seven children are alive and healthy, the last one having been born in October, 1893 She was of temperate habits, had enjoyed good health, and had had no previous trouble in her labours. She now considered herself to be eight months pregnant, her catamenia having been regular up till the last week in March, when the last period took place; she had noticed that she had not increased in size during the last month. Six weeks previously she had been alarmed by one of her neighbours waking her in the morning to tell her that another neighbour had fallen downstairs and injured herself. She dressed hurriedly in order to render assistance, but on reaching her kitchen she was seized with a sudden faintness and became conscious of a peculiar sensation, as though "something had turned over in her womb." After lying down for the day, however, the faintness passed off, and she went on in good health up till Dec. 1st. On the afternoon of that day she did a good deal of scrubbing, and in the evening had epistaxis, to which she was not liable. On the morning of the 2nd she was awakened at 6 A.M. by uterine pain, described as a "distended, stretched sensation," continuous in character, and accompanied by faintness and by an enlargement in the size of the uterus. This pain continued throughout the morning, and on attempting to rise about 2.30 P.M. to micturate she fainted, and I was accordingly sent for. On my arrival at 4 P.M. I found her anæmic, with dark circles round the eyes. The pulse was 126 per minute and of low tension. The uterus reached within three inches of the costal margin and was extremely tense to the touch, but not tender; there was continued uterine pain, with no rhythmical exacerbations. Per vaginam the cervix was found to be softened, the external os patulous, and the internal os closed. The finger could be coaxed through, however, and the membranes felt, with the fœtal head presenting. On withdrawing the finger a little bright blood was noticed on it, but whether this was the effect of dilating the os, or whether it had previously been passed into the vagina, could not be determined. A diagnosis of concealed accidental hæmorrhage being fairly obvious, the membranes were at once ruptured with a probe and the liquor amnii (unstained with blood) was let out, a drachm and a half of the liquid extract of ergot was given by the mouth, and the os dilated with the fingers. The uterus acted well, and at 8 P.M. a dead fœtus was delivered. The placenta was expressed, and with it two large clots were expelled. The fœtus was apparently about seven and a half months old and had evidently been dead some little time, the epidermis being sodden and easily detached, and the cranial bones loose; it measured 16½ in. and presented nothing of note. On examining the placenta, which measured 6¾ × 5½ in., a roughly oval depression 4 × 3¾ in. was noted on it. This depression was half an inch below the general surface, and over it the normal placental structure was atrophied, producing a fibroid, nearly smooth base; it reached the point

Digitized by Google

of junction of the placenta and chorion at one point only, the latter being stained with clot for half an inch beyond. The opening in the membranes through which the fœtus had escaped was almost central. On examining the clots a portion of the smaller was found to be obviously old, being firm and partially decolourised, and this portion fitted with considerable exactness into the placental depression; around and on one side of this clot recent clot had been deposited. The larger clot, which measured 9 in. × 6 in. × 2 in., was recent. It would appear, therefore, that the original hæmorrhage six weeks previously had separated sufficient of the placenta to destroy the fœtus and had produced by pressure the depression noticed, and that a second hæmorrhage had given rise to the symptoms which caused the patient to seek medical advice. No local cause in the fœtus or placenta, and no general cause in the mother, could be found to account for the hæmorrhage. It only remains to add that the patient, though considerably blanched and with a pulse-rate of 142 immediately after delivery, made a steady recovery and was convalescent on Dec. 16th.

Caterham Valley.

RECURRENT CANCER OF THE STOMACH.

BY W. H. CARTHEW DAVEY, M.R.C.S., L.R.C.P. LOND.,
ASSISTANT SURGEON, CHILDREN'S INFIRMARY, LIVERPOOL.

IN THE LANCET of April 12th, 1890, I reported a case of carcinoma of the pylorus for which pylorectomy was performed, and in which the patient recovered, the operation having been done by Mr. Rawdon. I regret now having to report the death of the said patient, five years after the operation. I believe the case is unique, so far as recurrence and prolongation of life are concerned. Mr. Jacobson, in "Operations of Surgery," quoting Mr. Butlin, says: "All save one died in a period of from four to eighteen months. The exception was one of Woelfler's cases, which remained well for a year and then had recurrence in the cicatrix, which was operated on. Later, the glands of the groin became affected, and four years after the pylorectomy the patient was dying slowly of cancerous recurrence." The history of the present case is briefly as follows. After the operation the man remained perfectly well for three years and a half, with no dyspepsia or gastric trouble whatsoever, and could take any kind of food without discomfort, when in June, 1893—that is, just three years and eight months after the operation—he was prostrated with an attack of hæmatemesis. The hæmorrhage soon ceased with the usual remedies, and he apparently recovered perfectly. There was no tumour or sign of any fresh growth to be felt at the epigastrium. This attack of hæmorrhage was the first evidence we had of recurrence; it was, to say the very least, disappointing, as we were congratulating ourselves on the non-recurrence of the disease, hoping we had eradicated it, so long a time having elapsed since the operation (close upon four years). Some six months after the hæmorrhage symptoms of dyspepsia presented themselves, and one could now feel a small tumour just beneath the old cicatrix in the skin. This gradually increased in size. He began to lose flesh, and it was now evident that the disease was making rapid progress, for he was no longer able to sit up, and, taking to his bed, he gradually sank and died from suppurative meningitis and exhaustion on Dec. 21st, 1894. The necropsy showed a large excavating ulcer, with indurated edges and sloughy base, infiltrating nearly the whole of the mucous membrane of the stomach. The stomach was adherent to the liver, pancreas, and diaphragm—in fact, one had to remove these organs with the stomach, as the adhesions were so firm that it was quite impossible to dissect it off without tearing. There were no secondary growths in any of the organs. The disease appeared to be quite localised to the stomach. The suppurative meningitis would no doubt be due to septic embolism from the sloughing mass in the stomach. Microscopical examination showed the cancerous nature of the growth. Dr. Barendt, pathologist to the Royal Southern Hospital, very kindly assisted me at the necropsy.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF OBSTINATE HICCOUGHING WHICH CONTINUED FOR TWELVE DAYS WITHOUT INTERMISSION.

BY P. SLEVIN, L.R.C.S., L.R.C.P. IREL.

ABOUT two years ago I was called to see a man aged seventy-eight, of remarkably fine physique, who had enjoyed good health all his life, with the exception of an occasional attack of gout. I found him suffering from great prostration, with gastric catarrh and hiccough. Thinking the latter was caused by the catarrh, I prescribed a suitable diet and gave him a mixture of bismuth with some morphia. On arriving next morning I found him more prostrate and the hiccough as persistent as ever, the latter symptom being as active during sleep as in a waking state. I tried chloral, bromide of potassium, hypodermic injections of morphia, and atropia over the epigastrium, ice pressure on the carotids, and, in fact, every remedy of any repute for that complaint, but each morning I saw him he was hiccoughing as persistently as ever. He then consulted a well-known London consultant, who wrote to me recommending a large blister over the sterno-mastoid; this I did not apply, as I thought the remedy too severe. On the evening of the twelfth day of the hiccough I thought of exciting a new reflex, so procured him a box of very pungent snuff. He took several pinches during the night, which produced sneezing. On the following day I found him in the best of spirits, being quite free from the hiccough. He has not had any return of the troublesome affection since.

West Drayton.

A CASE OF ACUTE ŒDEMA OF THE LUNGS.

BY HENRY WALDO, M.D. ABERD., M.R.C.P. LOND.,
PHYSICIAN TO THE BRISTOL ROYAL INFIRMARY.

ON June 12th, 1895, a male patient aged thirty-one was admitted to the Bristol Royal Infirmary. He was well nourished and of good physique. He told me he had been out of work for some time and had lived poorly, chiefly upon bread. There was no alcoholic history. He complained of pain in the chest after food and nausea. His temperature at the time of his admission was normal, but at 8 o'clock the same night it was 101·2° F. The following morning at 8 o'clock it was 100·6°, and at 12 noon 102·4°. There was no rigor or chilliness. The skin was dry. The legs were moderately swollen and "pitted" on pressure. He was somewhat anæmic. His back, abdomen, and thighs were covered with petechiæ, which I took to be purpuric. Upon examining his retinæ there were no visible hæmorrhages. The cardiac sounds were clear, with no audible murmurs. The gums were in a natural condition. The urine did not contain albumen. After being in bed for twenty-four hours he quite suddenly became breathless and cyanosed, a condition which was attended with incessant coughing up of a scanty pink frothy fluid. Râles were heard all over the chest, and he complained of feeling suffocated. This condition of things lasted for two hours and a half, when he died. At the necropsy (twenty-four hours after death) the liver was found to be soft and looked fatty. The spleen was large and pulpy. The stomach was empty and distended with gas. The intestines were almost empty. There were hæmorrhagic spots all through, from the œsophagus to the rectum, and in some parts of the small intestine the hæmorrhagic surface was rather widespread, extending for 6 or 8 inches in several places. The heart was normal, with the exception of the tricuspid orifice, which was rather distended, and the aorta was decidedly small in calibre. There were 2 or 3 oz. of clear fluid in the pericardium. The kidneys were healthy. The brain was normal, although the lateral ventricles were distended. Both lungs were most actively engorged with blood and very œdematous (fluid pouring out of an incision abundantly). There were no signs of infarcts. The left lung was adherent

Digitized by Google

to the chest wall. Such a case as this leads one to believe that "active congestion" of the lungs, distinct from pneumonia and from phthisis, is a real malady.

Clifton, Bristol.

A NOTE ON A SIMPLE MANNER OF OVERCOMING THE CATARRH CONSEQUENT ON THE ADMINISTRATION OF POTASSIUM IODIDE.

By GEORGE COHEN, M.B. EDIN.

I HAVE often observed that patients taking iodide of potassium suffered in a marked degree from "iodism," the chief symptoms being coryza with a sometimes profuse discharge, sneezing, pains over the frontal sinuses, swelling of any part of the mucous membrane of the mouth, and a sense of heat in the chest. The foregoing phenomena are identical with those attendant upon the inhalation of free iodine (Mitchell Bruce), and it has been observed that one is more likely to be attacked with catarrh if the iodide of potassium contains free iodine as an impurity. This seems to justify the belief that the catarrh of iodism is due either to iodine being secreted by the salivary glands or to the circumstance that iodide of potassium is broken up in the mouth after its secretion and free iodine liberated. The latter view is supported by Schmeideberg, who has proved that iodide of potassium in the presence of carbonic acid is decomposed, the latter being abundant in the expired air in the region of the salivary glands. Whilst taking charge of Dr. Herschell's out-patients at the National Hospital for Diseases of the Heart, I have been able to stop the catarrh in three well-marked cases by adding to the mixture (being in each case ten grains of iodide of potassium and half an ounce of water) five minims per dose of tincture of belladonna, my object being to reduce the salivary secretion, and in each case the result was satisfactory. Any antisialagogue would doubtless have a similar effect, but belladonna is, in my opinion, the most useful, as it can easily be given in the form of a mixture with the iodide, and in the small dose that is used in such cases it counterbalances the so-called "depressant" action of the potassium.

Bella autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, Lib. iv. Proœmium.

GREAT NORTHERN CENTRAL HOSPITAL.

A CASE OF S-SHAPED DISTORTION OF THE SEPTUM NASI SUCCESSFULLY TREATED BY A SERIES OF OPERATIONS AND THE USE OF RETENTIVE APPARATUS.

(Under the care of Mr. W. SPENCER WATSON.)

THE account of this case of operation for deformity of the nose is of interest, as such cases do not often present themselves for treatment. The deformity resulting from an injury such as that described below is usually remedied soon after the accident by the surgeon who is called in, and at that time it is easy to replace the damaged parts. Mr. Watson's case shows how difficult it may be to remedy the displacement when some years have elapsed before application is made for relief and when the accident was inflicted at an early age.

A young woman aged nineteen was sent by Mr. Charles Wray to consult Mr. Watson about a twist of the nose to the left dating from early infancy. She was a well-grown and well-nourished girl of healthy and comely aspect, which, however, was marred by the want of symmetry of the nose. The twist commenced at the point of junction of the cartilaginous septum with the lower border of the nasal bones, which retained their central position. Both the upper and lower lateral cartilages of the left side were thrust outwards by a thickening of the left side of the septum, and were also more prominent than in the normal condition from thickening and enlargement. The disfigurement was, therefore, very marked, but there was also much obstruction to the breath-channels of both sides from thickening and twisting of the septal cartilage, the right side being, however, more obstructed than the left. This was due in great measure to the posterior convexity

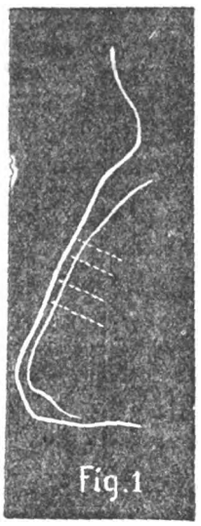

Fig. 1

of the S-shaped curve being very pronounced in the back of the right fossa, and also to the presence of an enlargement of the inferior turbinal of that side. The patient was one of a family of nine, all of whom were healthy and without any facial deformity. She attributed the disfigurement to an injury received when an infant. She and her brothers and sisters were playing, and she was thrown to the ground, striking her nose with considerable violence.

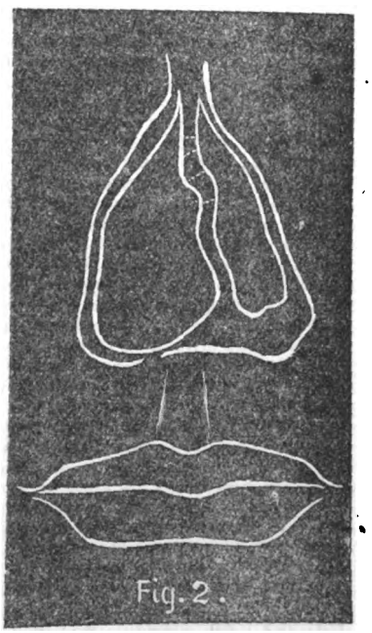

Fig. 2.

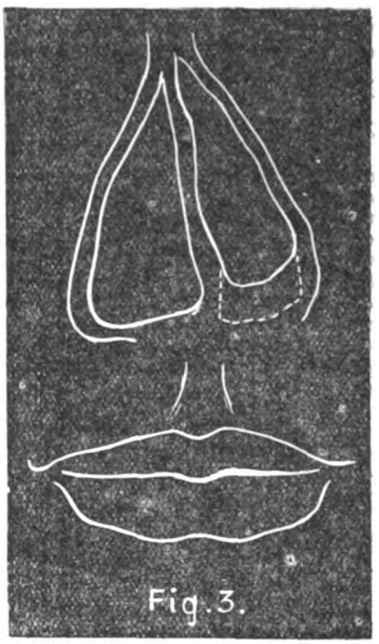
On April 26th, 1894, she was ordered to wear a No. 5 vulcanite nasal plug several hours each day in the left nostril. She continued to do so till May 4th, when Adams' septal compressor was substituted. These measures were taken as preliminaries, in order that the nasal mucous membrane might be rendered accustomed to their use after the intended operations. With the same view a nose truss was applied to the skin surface and worn for a certain time every

Digitized by Google

nose was in a central position and showed no sign of returning to its faulty position when the truss was removed. The outward contour was perfectly symmetrical. There had been no return of the neuralgia, or of any untoward symptoms, and very little pain had been complained of. From this date until Sept. 21st the truss was worn for an hour or two every day. The position of the nose remained central, with, however, a scarcely noticeable prominence of the left side. The patient and her friends were very well pleased with the result. There were still some adenoids in the pharyngeal vault, and she was, therefore, directed to apply with a throat brush a solution of perchloride of iron in glycerine night and morning. On Nov. 7th there was some post-nasal obstruction, and this was found to be due to hypertrophic enlargement of the inferior turbinal on the right side. A fourth operation was now performed. Cocaine was applied, and a portion of the hypertrophied turbinal of the right side was cut away by the use of Walsham's angular nasal scissors. The bleeding was not great, but



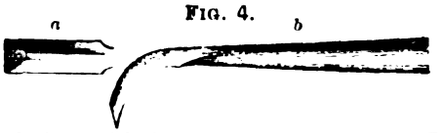


Fig. 3.

in order to avoid trouble the nostril was plugged with eucalyptus gauze. On Nov. 29th the patient said her breathing was free, and there were no pharyngeal crusts or other troubles such as she had previously experienced. On posterior rhinoscopic examination there was seen a somewhat prominent portion of the inferior turbinal of the right side. She was directed to use a spray of borax, soda, and common salt with oil of eucalyptus globulus. On Dec. 12th the obstruction in the right nostril had quite disappeared and the nose remained symmetrical. When last seen, on March 14th of the present year, the improvement in her condition remained. She was seen by Mr. C. Wray, who was much pleased and rather surprised at the result. She was seen again on May 12th, when the improved appearance was still maintained and the breath channels remained perfectly free.

Remarks by Mr. SPENCER WATSON.—This case presented complications and consequently required a greater number of operations

FIG. 4.

a, back view, and *b*, side view of scaling instrument. The width of the blade is somewhat exaggerated in the illustration.

which, though tedious in description and some of them novel, were not severe and were not complained of as painful by the patient. The principal novelty in the treatment was the use of the rectangular dental "scaling" instrument for the division of the partly bony and partly cartilaginous dorsal ridge. (See Fig 4.) In order to appreciate this part of the

treatment it must be borne in mind that the upper lateral cartilages, which are generally described in anatomical works as separate from the septum, are really united to it and form with the septal cartilage a single piece, the ridge of the dorsum of the nose being, in fact, the union of these lateral pieces with the septum, and when, as in the present case, this ridge is thickened and distorted it offers a formidable obstacle to the ordinary methods of restoring the symmetry of the parts. The ordinary resiliency of the cartilage is much greater the thicker it becomes. Hence it is necessary to make cross cuts in it at right angles to the line of deviation, and then by the use of the nose truss and plugs to retain the divided ridge in position until the faulty resiliency and distortion have been overcome by union in the central position. This method was resorted to rather late in the case because my attention was in the early period diverted to the distortion of the deeper parts, which were much thickened and seemed to offer the greatest resistance to attempts at restoring symmetry. Had I recognised the importance of the thickened dorsal ridge at an earlier period the two methods of operating might with advantage have been combined in one proceeding. This would have shortened the treatment, but might also have rendered the use of retentive apparatus less easy. On the whole I think in a similar case much the same methods would have to be employed, but the attack on the dorsal ridge might be commenced sooner and with more precise aims in the light of the experience gained. The nose truss employed in this case was a modification of Mr. Adams's depicted in the second edition of my work on Diseases of the Nose at p. 251. The pads, however, were not kept in their positions by levers and cogwheels, but by springs attached to the frontal band. I am indebted to Mr. Kendall, house surgeon of the Great Northern Central Hospital, for his skilful assistance in the management of the case. The figure of the dental scaling instrument and the instrument itself were kindly lent to me by Messrs. Ash and Sons of Broad-street, Soho.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

Adjourned Discussion on the Development of the Human Placenta.—Placental Polypus.—Exhibition of Specimens.

A MEETING of this society was held on July 3rd, Dr. F. H. CHAMPNEYS, President, being in the chair.

On the resumption of the adjourned discussion on Dr. Eden's Demonstration on the Development of the Human Placenta, Dr. DAKIN asked Dr. Eden how the specimens of placentæ and deciduæ from which the sections were made had been obtained and prepared, so as to exclude the possibility of the hæmorrhages into the deciduæ in the earlier stages being artificially produced. It was highly probable that the hæmorrhages were normal, for the process thus resembled that of the formation of the menstrual decidua, which was another example of intense activity of function. The resemblance was interesting as bearing on the connexion of ovulation with menstruation. Hæmorrhages as part of an early stage in the formation of the placenta were known from the observations of Hubrecht and others to take place in the trophoblast of some of the lower animals, where cleavage occurred in this part of the chorion; and produced spaces which became filled with maternal blood. Dr. Eden had said that what had been described as multinucleated cells by many observers were practically always sections of buds of the chorionic villi lying in the sinuses. These cells had, however, been demonstrated in the sinuses of the uterus itself and more deeply than the villi were likely to penetrate, and had been described by Helme as collecting around the vessels in the uterine wall towards the end of pregnancy in connexion with the hyaline degeneration of the sinus epithelium which took place then. This change had been first described by Friedländer and in the Society's Transactions by Sir John Williams.[1]—Remarks were made by Dr. GRIFFITH and Dr. GALABIN.—Dr. EDEN, in reply, said that the specimens of early ova shown at the last meeting might be fairly regarded as healthy; they were examples of abortion occurring from accidental causes, not from intrauterine disease. In answer to Dr. Galabin, he said that the maternal vessels became to a great extent opened up by the destructive action of the trophoblastic buds, and this process was the principal factor in the development of the circulation through the intervillous spaces. Similar changes had been described in the development of the placenta of many other animals besides man. The question of fibrinous and calcareous degeneration in the placenta he hoped to discuss in a subsequent paper.

Mr. ALBAN DORAN read a paper on Placental Polypus. In examining the clots from tubes which he had recently removed in cases of suspected tubal gestation, he compared the clots with sections of true placenta and of retained placental fragments. He also examined, for the second time, sections from a polypoid growth found in the uterus of a woman aged twenty-nine who died many years ago after the removal of a cystic kidney by Sir Spencer Wells. There had been no hæmorrhages; in fact, the patient believed that she was pregnant on account of the absence for several months of menstruation. The uterus, with the polypus attached to its wall, and the ovaries showing a large corpus luteum on one side, are preserved in the Museum of the Royal College of Surgeons of England (No. 4659, Pathological Series). In 1877 Mr. Doran believed that the polypus was a cavernous angioma. Dr. Boldt has, it must be noted, quite recently detected a tumour of that kind in the uterus. The College specimen, however, proved on careful examination to be made up of placental tissue. It is a true placental polypus. In all other recorded cases uterine hæmorrhage was present. He dwelt on recent opinions concerning placental polypus. According to the recent researches of Klasson of Kieff, and Lejars and Lévi of Paris, the so-called "fibrinous polypus" is only a form of placental polypus, if not identical, the placental tissue having been overlooked. He finally referred to Hartmann and Toupet's important investigations on the results of retention of placental tissue when, instead of septic changes, organisation occurs. They find that this tissue may develop into innocent deciduoma (that is, placental polypus), hydatidiform mole, and chorion-celled sarcoma. This last growth is the "malignant deciduoma," or cancer following gestation, which has been so frequently described of late, on indisputable evidence, by Continental authorities. Mr. Doran asked why, if this grave disease be so frequent in Europe, it has hitherto escaped the notice of British teachers and practitioners.—Dr. HERBERT SPENCER had six years ago met with a case which he believed to be of the nature of the deciduoma malignum of Continental authorities. A woman about twenty-five years of age died two months after delivery with symptoms of septicæmia and signs of uterine cancer. During life several pieces of putrid "placenta" had been removed. At the post-mortem examination growth and ulceration were found in the situation of the placental site, where the wall was almost eaten through, and also (unlike most cases) in the cervix. The microscopic examination of the uterine growth was somewhat unsatisfactory, but it appeared to be sarcomatous. In the lungs there were many secondary growths, some as large as a walnut; under the microscope they were evidently sarcomatous. He had hoped to meet with another case in which the microscopic examination of the primary growth would be more satisfactory; but as the above-mentioned appeared to be the only case of the kind in this country he would be happy to bring it before the society. The specimens were in University College Museum.—Remarks were made by Dr. GALABIN and Dr. GRIFFITH.—In reply to Dr. Galabin Mr. ALBAN DORAN said that hydatidiform moles undoubtedly displayed malignant characters in certain cases. They were myxomatous, but it must be remembered that general pathologists are not all agreed as to the limits of the term "myxoma." Sometimes mucoid tissue was normal and not in any sense a new growth; sometimes it was clearly associated with sarcoma. Dr. Griffith's tumour seemed to be a true fibrinous polypus, as no placental tissue was detected in its substance. Dr. Herbert Spencer's case was of the highest interest; it appeared to be the first instance of malignant deciduoma in the British Isles. In conclusion, Mr. Doran recommended careful inspection of all specimens of malignant disease of the uterus from patients under forty already preserved in museums. In future, in any patient of this kind close inquiry should be made as to the occurrence of abortion within a few years of the appearance of evidence of malignancy.

[1] Vol. xx., p. 172.

Digitized by Google

The following specimens were exhibited :—

Mr. DORAN (for Mr. BRADBURY and Dr. LOWE) : A Monster, Acardiacus Paracephalus.

Dr. BLACKER : Uterus affected with Fibroids and Carcinoma of the Cervix obtained eight years after Oöphorectomy.

Mr. TARGETT : (1) Abscess in Ovary caused by direct Infection through Connective Tissue ; and (2) Casts of Vaginal Mucous Membrane.

Dr. AMAND ROUTH : Macerated Skull of an Anencephalic Fœtus.

Dr. CULLINGWORTH : Pedunculated Fibro-myoma of the Broad Ligament with Twisted Pedicle.

Dr. PLAYFAIR : Tubal Abortion.

Dr. GALABIN : (1) An Improved Form of "Sanitary Towel" ; and (2) Pregnancy in a Rudimentary Uterine Horn.

In the report of the proceedings at the June meeting of the society it should have been stated that the President announced that the General Medical Council had approved of a form of certificate to be given to candidates successful at the society's examinations in midwifery. Copies of the form were handed round.

OPHTHALMOLOGICAL SOCIETY.

The association of certain forms of Myopia with Disease of the Nose and Pharynx.—Exhibition of Cases.

THE annual general meeting of this society was held on Thursday, July 4th, Mr. E. A. BROWNE, the Vice-President, being in the chair.

Dr. RAYNER BATTEN read a paper on the association of certain forms of Myopia with Disease of the Nose and Pharynx. After referring to a former paper read before the society in July, 1893, in which he held that certain constitutional diseases produced myopias distinguishable and differing from each other according to their cause, he proceeded to describe a special form of myopic fundus which he associated with certain diseases of the nose and pharynx. The chief characteristics of this form of myopia were (1) the existence of localised posterior staphylomata at or in the immediate neighbourhood of the optic disc, or on the nasal side of the fundus ; (2) the tilting of the optic disc in the direction of the staphyloma ; and (3) the œdematous condition of the more prominent margin of the optic disc. This œdema, or "pseudo-neuritis," he considered as secondary to and caused by the tilting of the disc. The conditions of the nose and throat with which he associated this form of fundus were adenoid vegetations, enlarged tonsils, deviation of the septum, blows on the nose and forehead, ozœna, syphilitic disease of the nasal bones, and chronic otorrhœa. He quoted cases in which myopia had immediately followed the onset of some of these conditions, and in conclusion said that the presence of the œdema was generally a sign that the cause was still in active operation, that the visual acuity was seldom good in these cases, even when the degree of myopia was low, and was especially bad when the staphyloma was on the nasal side of the optic disc, that the whole condition was one indicative of a progressive myopia, and that the œdema and tilting both tended to disappear with the progress of the myopia.—The CHAIRMAN, in commenting upon the subject of the paper, considered that the evidence adduced was insufficient to convince those who had not given it special attention. Many constitutional causes required to be eliminated, such as scarlet fever or rheumatic fever, as well as other exhausting diseases, before myopia could be reasonably attributed to a local lesion.—Mr. SPENCER WATSON was disappointed that Dr. Batten had not put forward a theory to explain the relationship between nasal disease and myopia. He was disposed himself to regard both conditions as dependent upon some common constitutional cause. He quoted instances where interstitial keratitis had been followed by myopia in constitutional syphilis, indicating, he thought, that there was softening of the whole eye.—Dr. BATTEN, in reply, said he had dealt with constitutional causes in a previous paper. The connexion between the sphenoidal cells and fissures and the blood supply to the eye was very close. The eyeball should be regarded as an end organ, and interference with its blood-supply was likely to lead to changes analogous to those produced in clubbed fingers.

Mr. ADAMS FROST showed a complete set of instruments which had belonged to an Indian oculist, and which had been presented to the society by Surgeon-Colonel Drake-Brockman. Describing the method of operating, he stated that there was no attempt at asepsis or even ordinary cleanliness ; the lower lid was everted, a puncture made in the ciliary region with a lancet, and the lens couched by passing an instrument through this incision. The whole performance was done under a cloth, and most eyes were lost by panophthalmitis or secondary glaucoma.—Surgeon-Colonel DRAKE-BROCKMAN said that these instruments were handed down from father to son for generations and were extremely difficult to secure. Less than 10 per cent. of the operations could be considered successful cures.

The following cases and card specimens were shown :—

Dr. E. H. CARTWRIGHT : Modification of Thomas's Arrangement of Holmgren's Wools.

Mr. FISCHER : Symmetrical Ulcers of both Cornea.

Mr. D. MARSHALL : Double Enophthalmos.

The following gentlemen were elected as office-bearers and members of the Council for the session 1895-96 :—President : E. Nettleship. Vice-Presidents : Stephen Mackenzie, M.D., Henry Power, Edgar A. Browne (Liverpool), Thomas Barlow, M.D., G. Anderson Critchett, J. B. Story (Dublin), John Couper, G. A. Berry, M.D. (Edinburgh). Treasurer : George Cowell. Secretaries : Samuel Herbert Habershon, M.D., John Bowring Lawford. Librarian : W. Adams Frost. Other members of Council : M. A. Adams (Maidstone), Charles E. Beevor, M.D., T. H. Bickerton (Liverpool), Ernest Clarke, M.D., A. Deas Davidson, M.D. (Swansea), E. F. Drake-Brockman, A. Hill Griffith, M.D. (Manchester), Gustavus Hartridge, Joseph Nelson, M.D. (Belfast), D. Argyll Robertson, M.D. (Edinburgh), A. E. Sansom, M.D., James Taylor, M.D. At the same time Dr. J. S. Bristowe, F.R.S., was elected an honorary member of the society.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

Exhibition of Cases.—Treatment of Fractures.—Ruptures of the Pancreas.—Alcoholism and its Effects.

THE thirteenth meeting of this society was held on July 3rd, Dr. CLOUSTON, President, being in the chair.

Dr. W. ALLAN JAMIESON showed a case of Hydroa Vacciniforme in a girl aged seven. The eruption was limited to the exposed parts—the hands and face. It had persisted two years, being worst in the warm months. The aspect of the rash closely resembled impetigo contagiosa. A case of Ichthyosis illustrating the effects of purely local treatment was also shown.—Dr. NORMAN WALKER showed a case of Lichen affecting the back in a small boy.—Dr. JAMES showed a boy who had been trephined for a Compound Fracture of the Skull some months previously. There was now a considerable interval in the bony skull. The pulsation of the brain could be easily perceived, and was demonstrated by means of a water manometer. The column of water rose and fell with the pulse and with the respiration. On muscular effort and holding the breath the water rose. Very slight mental effort was required to produce extra bulging and extra pulsation. The slightness of the stimuli necessary to cause alteration in the pressure was remarkable. Dr. LEITH showed :—1. A Ruptured Pancreas and Rupture of the Duodenum at the duodeno-jejunal junction ; a Rupture of the Liver ; and a Rupture of the Kidney, all caused by direct violence. 2. A Brain with Multiple Tuberculous Tumours of the Cerebellum. The symptoms during life gave rise to doubt between bulbar paralysis and general paralysis of the insane. The brain also showed chronic hydrocephalus from pressure on the veins of Galen. 3. Photographs and specimens from a case of Omental Hernia, Perforative Appendicitis, and Retro-cæcal Abscess.—Mr. A. G. MILLER showed an Abscess in the Temporo-sphenoidal Lobe, the result of middle-ear disease.—Dr. EDWARD CARMICHAEL showed a specimen of a Sarcoma of the Skull. The convolutions of the brain were compressed, but there had been no symptoms till within a few weeks of death.

Mr. A. G. MILLER read a paper on the Treatment of Fractures near a Joint aided by Massage and Movement. He quoted the recent opinions of Mr. Arbuthnot Lane and Mr. Marmaduke Sheild in relation to the unsatisfactory nature of the ordinary treatment of fracture near a joint. He agreed that the present treatment was unsatisfactory, as the limb was frequently stiff and comparatively useless for

Digitized by Google

a considerable period. He believed the cause of this to be the long period of rest maintained for the treatment of the fracture. In the case of a fracture near a joint there was generally a double injury—both joint and bone were injured. The fracture was treated and the sprain was ignored. Rest alone would not cause ankylosis, but rest and injury would. In the case of a Pott's fracture, for example, besides the fracture of the tibia there was tearing of ligaments, damage to synovial membrane, and effusion into and round the joint. Such an injury should be treated with rest for the fracture and movement for the joint. A box splint should be applied, taken down twice a week and massage applied, and passive movement carried out with every precaution. The advantages of such a combination of rest, massage, and passive movement were that swelling was rapidly got rid of, adhesions were prevented, and time was saved. A patient was shown on whom this treatment had been carried out with excellent results.—Mr. JOSEPH BELL from a study of recent literature thought the young surgeons were laying on themselves a burden of responsibility which they had no right to do when they implied that fracture should be treated with absolute success. There were certain fractures in the vicinity of joints from which, do as they like, they would have bad results. In fractures at the elbow in young people he thought that they should be kept quiet for one day for each year of the child's age. He never used splints in Colles' fracture. He had treated a case of Pott's fracture recently with full and free massage from the beginning, with excellent results.—Dr. LAING said that as soon as effusion into the joint was over massage should be begun, and in the case of a sprain movement might be begun on the second or third day. A patient with a bad sprain should be able to walk in a week. Fracture was much better and sooner mended with massage than if left in a stiff splint the whole time.—Mr. ALEXIS THOMSON and Mr. STILES spoke.

Dr. LEITH read a paper on Ruptures of the Pancreas, their relations to Pancreatic Cysts, with some remarks upon Treatment. He remarked on the position of the pancreas and the difficulty of reaching it by injury. In most cases there was rupture of a more important viscus, but in two recorded cases in which this did not take place there was little hæmorrhage, and had the patient survived there was no reason why the rupture should not have healed. What hæmorrhage there was was into the sac of the lesser omentum, and a cyst might be formed. The post-mortem evidence of this was not conclusive. In the treatment of pancreatic cysts aspiration was deprecated. Drainage was the best treatment. Some of the cysts were best reached from behind. He described the method of operation.—Mr. COTTERILL had used the method in a case in the previous week.—Mr. BELL also spoke.

Dr. A. LOCKHART GILLESPIE gave statistics concerning the patients admitted into the Royal Infirmary suffering from Alcoholism and its Effects during the last five years. The statistics were founded on over 1000 cases. The tables showed an increased number of admissions after the trades holidays. It was found that outside workers were most numerous in summer, and inside workers in winter. The numbers of drivers, coachmen, &c. were greatest in the wettest months. Peripheral neuritis had occurred as often in men as in women. Delirium tremens and pneumonia were most common in July.

Reviews and Notices of Books.

The Malarial Fevers of Baltimore. By WILLIAM SYDNEY THAYER, M.D., and JOHN HEWETSON, M.D., Assistants in the Medical Clinic of the Johns Hopkins Hospital. Baltimore: The Johns Hopkins Press. 1895.

THIS work, of 215 pages, and illustrated with some excellent plates, is reprinted from the Johns Hopkins Hospital Reports, Vol. V., 1895, and is an analysis of 616 cases of malarial fever, with special reference to the relations existing between different types of hæmatozoa and different types of fever. The work is of an exhaustive character, and embodies the results of an extended series of clinical and bacteriological observations and researches. There were 616 cases of malarial fever treated in the wards and in the out-patient medical department of the hospital during the five years from 1889 to 1894. The examination of the blood in a considerable number of the cases occurring in the out-patient department, having commonly been too hasty or insufficient, has not been included in the authors' analysis, but in all the cases treated in the wards of the hospital the specific micro-organism was, we are told, discovered. As a result of their observations the authors believe that they "have been able to recognise certain distinct types of parasites which appear to be related in turn to certain almost equally characteristic types of fever." The principal object of their paper is, they tell us, to determine by a careful analysis of all the cases how far these impressions may be justified, and to compare these results with those of other observers. The work, moreover, contains an historical summary of the more important literature concerning the malarial parasite and a fairly complete list of the publications that have appeared since the parasitic origin of malarial fever has been recognised, as well as references to works and articles on the hæmatozoa of birds and other animals. It will be seen from the foregoing that the authors have not only produced a very exhaustive and useful treatise for all engaged in these bacteriological studies, but they have also done original work and undertaken a large amount of scientific observation in connexion with the varieties of hæmatozoa found in the malarial fevers of Baltimore. Almost all their examinations were made with fresh specimens of blood, which, when carefully and properly carried out, have always seemed to the authors to be simpler and more satisfactory than the different staining methods, although they have had recourse to these in many instances. The method of conducting their observations and the precautions which must be rigidly adhered to are fully described. We notice that the authors prefer in practice to take the blood for microscopical examination from the lobe of the ear for reasons stated by them. In connexion with the researches which have been carried on in the medical clinic of the Johns Hopkins Hospital at Baltimore we cannot do better than refer our readers to the excellent paper by Dr. G. Thin on "The Parasite of Malaria and Malarial Fevers," with its coloured illustration, and to our leading article on the same subject, in THE LANCET of last week.

Malarial fever, relatively rare in Baltimore, as elsewhere, during the winter months, is stated to reach a maximum of prevalence in September, the majority of all the cases occurring in August, September, and October. The relative susceptibility of the negro is said to be less than that of the white population by nearly two-thirds. The varieties of the malarial parasite distinguished and described by the authors are: the tertian parasite, the quartan, and the æstivo-autumnal parasite. Nothing in their experience has led them to believe that these varieties are interchangeable: they are distinct varieties, though closely allied to one another biologically. Combined infections with parasites of different varieties may occur, though rarely. The crescentic bodies, associated with the æstivo-autumnal parasite, develop from the small hyaline forms. Our authors have seen nothing to support the views of Mannaberg that they are the result of conjugation. They have never seen sporulating forms which they believe to have developed from crescents, and are not inclined to accept the view that these are degenerate forms, but rather that their true nature is still undetermined. The nature of the flagellate bodies which may develop in all types of malarial fever is not yet determined. As regards the action of quinine, which is undoubted, upon those three varieties of the parasite, they say that its influence is most strongly exerted when the parasite is undergoing the process of segmentation, before the entrance of the fresh segments into the red corpuscles. The drug is best administered just before the beginning of a paroxysm if we wish to obtain the greatest effect with a single dose.

It is almost needless to add that in our opinion the work

Digitized by Google

under review is a very valuable contribution to the interesting series of investigations that have been published concerning Laveran's parasite.

Dictionary of National Biography. Edited by SYDNEY LEE. Vol. XLI., Nichols—O'Dugan; Vol. XLII., O'Duinn—Owen. London: Smith, Elder, and Co. 1895.

FROM the general reader's point of view the most interesting articles in Vol. XLI. are probably those on two politicians of widely different careers, who were nevertheless to some extent contemporaries. Stafford Henry Northcote, the first Earl of Iddesleigh, was born in London in 1818, and succeeded to a baronetcy in 1851. He first entered Parliament in 1855, became Chancellor of the Exchequer in 1874 under Mr. Disraeli (after whose death he led the Conservative opposition), was created Earl of Iddesleigh in 1885, and died in 1887. Daniel O'Connell, the "Liberator," was born in county Kerry in 1775, and was called to the Irish Bar in 1798. In 1800 he publicly identified himself with the agitation for the repeal of the union with Great Britain, and from that time until his death at Genoa in 1847 he was the leading political champion of the Irish Nationalists. In the words of the biographer, "few other men have possessed his personal influence, and no other man has used such influence with greater moderation or self-abnegation."

The medical biographies are neither numerous nor important. Brinsley Nicholson, born in 1824 at Fort George, Scotland, was the eldest son of B. W. H. Nicholson of the Army Medical Staff. Having studied medicine in Edinburgh University, he graduated there as M.D. in 1845, became an army surgeon, and served in the Kaffir War in 1853 and 1854, the war with China in 1860, and the Maori War, which ended in 1864. About 1870 he retired from the army, and in 1875 he edited for the newly formed New Shakspere Society the first folio and the first quarto of "Henry the Fifth." In 1886 he brought out an excellent reprint of Reginald Scot's "Discoverie of Witchcraft" (1584). He died in 1892, and his edition of "The Best Plays of Ben Jonson" appeared in the following year. Whitlock Nicoll, born in 1786, studied medicine at St. George's Hospital and gained the diploma of the College of Surgeons of England in 1809. The degree of M.D. was subsequently conferred on him by three several authorities—Marischal College, Aberdeen, in 1816, the Archbishop of Canterbury in 1819, and Glasgow University in 1826. Besides contributions to medical periodicals he published five medical and five theological treatises. He was elected F.R.S. in 1830, and died in 1838. William Nisbet, M.D. and F.R.C.S. Edin., published volumes on various medical subjects between 1787 and 1808. William Norford, born in 1715, became an extra-licentiate of the College of Physicians in 1761, practised in Suffolk, and was the author of essays on the Treatment of Cancer and also of Fever. He died in 1793. Edward Norris, born in 1663, graduated as M.D. at Oxford in 1695; he was elected a Fellow of the Royal Society in 1698, and a Fellow of the Royal College of Physicians in 1716. In 1699 he accompanied his brother, Sir William Norris, as secretary of his embassy to the Mogul Emperor in India. He afterwards practised medicine in Cheshire and died in 1726. William Northcote, who was a naval surgeon from 1757 till about 1783, wrote on "The Marine Practice of Physic and Surgery" (2 vols., London, 1770), and also brought out smaller works on anatomy and pharmacy for the use of naval surgeons. John Northleigh, born in 1657, graduated as M.D. at Cambridge University and practised at Exeter. His principal writings were in defence of James II. He died in 1705, and was buried in Exeter Cathedral, where there is a monument of him. John Nott, born in 1751, studied surgery in Birmingham and London, travelled much on the Continent, made a voyage to China, became an extra-licentiate of the College of Physicians in London, and ultimately settled in practice near Bristol, where he died in 1825. His works, which were numerous, consisted chiefly of fiction, poetry, and metrical translations of Latin poets. His versions of the poems of Catullus, Propertius, and Johannes Secundus Nicolaius are reprinted in Bohn's Classical Library. Edward Nourse was born in 1701 at Oxford, where his father had practised from 1686. He was elected F.R.S. in 1728, and in 1731 was appointed assistant surgeon to St. Bartholomew's Hospital, ultimately becoming the senior surgeon. He was the first surgeon at that hospital who gave regular instruction in anatomy and surgery. He died in 1761. Christopher Nugent, a native of Ireland, graduated as M.D. in France and practised at Bath. In 1764 he removed to London and was one of the nine original members of the Literary Club. He was highly esteemed by Johnson, Edmund Burke, and other celebrities, and became a Fellow of the Royal Society. He died in 1775. None of these names of departed medical worthies are so familiar to the present generation as that of Thomas Nunneley of Leeds, who studied medicine at Guy's Hospital and took the diploma of the Royal College of Surgeons in 1832, becoming a Fellow in 1843. He settled in practice in Leeds, where for twenty years he filled the post of surgeon to the Eye and Ear Hospital, and lectured on anatomy, physiology, and surgery in the Leeds School of Medicine. The only well-known scientific man noticed in this volume is Dr. Noad, who was lecturer on chemistry at St. George's Hospital from 1845 till his death in 1877, and wrote several works on chemistry and electricity.

Among celebrities in other and lighter branches of literature allusion may be made to Mrs. Norton, the poetess, of whom there is a kindly memoir by Dr. Garnett of the British Museum. A great sensation was created in 1836 by this lady's vindication of her character in the Court which in those days dealt with marital questions. The biographer, however, does not mention that her unhappy story has been related by Mr. George Meredith in "Diana of the Cross-ways." At the end of the book there is an account of the adventurous life of Edmund O'Donovan, well known as a war correspondent of the *Daily News*, and especially distinguished by his journey to Merv in 1879.

In Vol. XLII. the most important memoir is that of Sir Richard Owen, the naturalist. He was born at Lancaster in 1804, studied medicine in Edinburgh University and St. Bartholomew's Hospital, became a Member of the Royal College of Surgeons in 1826, and in 1827 was appointed assistant conservator to the Hunterian Museum. In 1832 his "Memoir on the Pearly Nautilus" directed general attention to his abilities; in 1834 he was elected F.R.S., and in 1836 received the appointment of first Hunterian Professor of Comparative Anatomy and Physiology at the Royal College of Surgeons, his lectures on these subjects being continued regularly down to 1856, when he relinquished his professorship and became superintendent of the natural history departments of the British Museum. His original work was henceforth mainly confined to fossil osteology, but in 1861 he published two volumes of essays and observations by John Hunter, compiled from copies of Hunter's MSS., the originals of which were destroyed by Sir Everard Home. In 1866 and 1868 he published in three volumes his encyclopædic work on the "Anatomy and Physiology of the Vertebrates." He had not been long in office at the Museum when he began to urge the necessity for obtaining more suitable accommodation for the collection under his charge, a project fully realised in 1880 and 1881, when the specimens were transferred to the Natural History Museum at South Kensington. He retired from official life in the close of 1883, was immediately created K.C.B., and died in December, 1892. Next in the order of professional eminence comes James Adey Ogle, born in 1792 in London, where his father

Digitized by Google

was a successful general practitioner. Having studied medicine in Edinburgh and London he settled in Oxford, where he graduated as M.D. in 1820, and was appointed mathematical tutor of his college (Trinity) in the same year. He was elected F.R.C.P. in 1822, physician to the Radcliffe Infirmary in 1824, and F.R.S. in 1826. He delivered the Harveian Oration in 1844 and was appointed Regius Professor of Medicine at Oxford in 1851. He died in 1857, leaving no published works beyond a pamphlet on university education. Two accoucheurs of last century, well known, though not in the front rank, were Sir Fielding Ould in Dublin and Dr. William Osborne in London. The latter in 1783 published "An Essay on Laborious Parturition, in which the Division of the Symphysis Pubis is particularly considered." Osborne was opposed to this operation, and Dr. Norman Moore, the learned, careful, and suggestive author of many of the best medical biographies in previous volumes, adds that "it is now never performed." It has, however, lately been revived, and in 1893 THE LANCET had several lengthy articles on the subject, and recorded at least nineteen successful recent cases; of these operations thirteen were performed at the Clinique Baudelocque in Paris during 1892,[1] at least five in the United States,[2] and one at the London Hospital by Dr. A. H. N. Lewers.[3] Among the numerous memoirs contained in the volume there are several others of exceptional interest, both medical and general.

Horses, Asses, Zebras, Mules, and Mule Breeding. By W. B. TEGETMEIER, M.B.O U., F Z.S., and C. L. SUTHERLAND, F Z.S. London: Horace Cox. 1895.

IN the preface to this book we are informed that upwards of four thousand works on horses and their utilisation have been published, of which number about one-half have been printed in Great Britain. But recently new animals—such as Prejevalski's horse and Grevy's zebra—have been discovered, species hitherto untamed have been pressed into the service of man, and new hybrids have been reared which hold out the promise of great usefulness, while a vast amount of information has been accumulated proving the advantages obtained from utilising the hybrid between the horse and ass known as the mule, in almost all civilised countries except England, in which country it is stated no book on this useful hybrid has ever been published. To supply this deficiency, besides furnishing some account of a number of solipeds, to demonstrate the great value and economy of the mule as a beast of draught and burden, that could be as advantageously employed in this country in agricultural and general draught purposes as it is by other nations, and by ourselves in all military operations abroad, was partly the object the authors had in view in publishing the little work recently issued.

About seventy pages are devoted to a description of horses, asses, and zebras, chiefly from a zoological standpoint, and the remainder of the book—a little more than seventy pages—deals with the utilisation of mules, so that it is not a work on the mule alone. It would be a mistake to assert that nothing has been written on the mule in this country, for an article is devoted to it in the "Encyclopædia Britannica," and two War Office publications deal with the subject in a very complete manner. Since the Crimean War, at any rate, the utility of the mule as a most useful animal in field operations has been fully recognised by our military authorities, and our little campaigns in remote and mountainous parts of the world have proved and justified this recognition. In the Crimean War we employed an immense number of mules, especially for transport and hospital purposes; and in Abyssinia, and more particularly in recent times in India, they have been invaluable as pack animals. Their endurance, sure-footedness, steadiness, and capability of doing hard work on meagre fare are well known to all who have had experience of them on active service, and these qualities render them preferable to horses for some purposes, though for others they are not at all fitted. In civil life in this country they are certainly little employed, though they have frequently been tried; there may be prejudice against them, but this would disappear eventually were they to be found as useful as horses in the everyday demands of town and country. There are objections to their employment for some kinds of work, and there would not be much economy in price between them and horses, as in those countries in which they are extensively in use they are more expensive than the latter. They are not nearly so well adapted for the saddle as horses, and for weight and strength the largest of them could not compete with the splendid Clydesdales and Shires that play such a large part in town traffic and agricultural labour. Then there is the peculiar asinine temper displaying itself now and again, no matter how gently some mules may be treated. But, as has been said, for hospital and general transport work in the field, and more particularly in hilly and rugged countries where forage may be scanty, no animal can compare with the hybrid between the male ass and the female horse.

The subject of the fertility of mules is touched upon in the book before us, and the instance of the female mule "Catherine," said to be still existing at the Jardin d'Acclimatation, Paris, which had offspring by a horse, is stated by one of the writers to be the only one of a *possibly* fertile mule that has ever come under his observation after a rather wide experience. Several instances, however, of female mules becoming pregnant are on record, and one of these cases is particularly interesting, as it was reported upon by a distinguished veterinarian, Professor Nanzio of the Naples Veterinary School, who published an account of it in 1873 under the title of "Altro Caso di Figliatiera di Una Mula, con l'Analisi del Suo Latte." This instance appears to have escaped the attention of recent writers on the subject.

The Management and Medical Treatment of Children in India. By EDWARD A. BIRCH, M.D. Brux., F.R C P. Lond., late Principal of the Medical College, Professor of Medicine, and Physician to the Medical College Hospital, Calcutta. Third edition. Calcutta: Thacker, Spink, and Co. 1895.

IT may suffice to say of this work that the present edition has been revised and enlarged, and that the author has successfully tried to convey a simple idea of the principles which should prevail in the rearing of children in India and in the treatment of their maladies in that country. The remarks on the management of the infant, nursing, principles of diet, dentition, artificial feeding and the diet of childhood, general hygiene, the nature and prevention of the more common diseases, on fever generally, and the examination of sick children, strike us as very good and judicious. We recognise that the circumstances under which families are so frequently placed in a country like India are a sufficient justification for the publication of a book of this nature. The information it contains cannot fail to be useful to parents and others possessed of ordinary intelligence and judgment under the conditions in which families are so often placed in situations abroad, where skilled professional aid is not always available, or until it can be made so. Mothers and nurses will be the better in any case for being acquainted with the principles of the topics we have indicated; and as regards children's diseases and their treatment the author has succeeded in producing a practical

and trustworthy guide, taking care, as he says, to err rather on the side of caution than otherwise.

LIBRARY TABLE.

The Great Eastern Railway Company's Tourist Guide to the Continent is a useful little book published at the low price of sixpence. It contains a clearly printed map of West Central Europe and the South of Scandinavia, with railway routes from Harwich *viâ* the Hook of Holland. Interesting information is given about Holland, Belgium, Germany, and Switzerland. The first three countries are eminently places in which to take a holiday; but Switzerland is spoiled, the hunting-ground of the cheap tripper, the Salvation Army, and the ingenious gentlemen who combine coöperative educational tours at so much per head with instructions by leading ministers and talk about reunion. Belgium, Holland, and the Ardennes are still unspotted, and the Harwich route is an easy and comfortable way to get there.

A Guide to the Income-tax Law and Practice, with Illustrative Cases of Returns, Accounts on Appeal, Repayment Claims, &c. By JOSEPH AFFLECK, Jun. Manchester: 72, Market-street.—This useful book, the work of an expert, appears at an opportune moment, when the gentlemen with the well-known buff papers are busily engaged depositing them at our doors. Commencing with a brief history of the income-tax, from its introduction to the present day, the author carefully and lucidly explains the many intricacies with which, as such, we are mostly only too familiar, and from which we usually turn in despair of the prospect of ever fathoming. The different schedules are ably treated, and Chapter XIII. will be found most useful to medical men, the author setting out *in extenso* a simple form of profit and loss account, showing how to correctly arrive at the proper amount to be returned for assessment. The chapter on partnerships, too, remarks on the large sums annually overpaid in income-tax through partners' neglect to take advantage of the provision for separate assessment to claim exemption or abatement. Not less valuable is the information as to the method to be adopted for claiming repayment of tax in those cases (and they are legion) where the profits have been over-assessed. Unfortunately, the price of the book is not stated; but it is well worth a few shillings to every man, and may save many pounds to not a few.

A Book of Detachable Diet Lists, for Albuminuria, Anæmia and Debility, Constipation, Diabetes, Diarrhœa, Dyspepsia, Fevers, Gout or Uric Acid Diathesis, Obesity, Tuberculosis, and a Sick-room Dietary. Compiled by JEROME B. THOMAS, A.B., M.D. Philadelphia: W. B. Saunders. 1895.—The author has drawn up appropriate diet lists for the use of patients suffering from the ten morbid conditions above mentioned, and has supplemented them by enumerations of the various solids and fluids which are to be specially avoided in each case. About a dozen copies of each of these ten lists are bound into a book, each leaf being perforated near the back, so that it can be torn out and left with the patient's nurse or friends. The idea is good, and the lists are copious, but they are in some respects more adapted to American than to English households. The sick-room dietary is also in leaflet form, and gives plain directions for peptonising several articles, and for making various beverages and soups.

The History of the Pennsylvania Hospital, 1751–1895. By THOMAS G. MORTON, M.D., Fellow of the College of Physicians, President of the Medical Staff and Senior Surgeon of the Pennsylvania Hospital, and President of the Philadelphia Academy of Surgery. Assisted by FRANK WOODBURY, M.D., Fellow of the College of Physicians, and Honorary Professor of Clinical Medicine in the Medico-Chirurgical College. Philadelphia: *Times* Printing House. 1895.—The province of Pennsylvania was occupied in the seventeenth century by Quaker settlers under energetic and conscientious leaders, and it soon became a prosperous community whose general tendency was highly favourable to well-considered works of philanthropy. The question of providing for the sick poor was seriously taken up in 1751 by Dr. Thomas Bond, who secured the coöperation of Benjamin Franklin and was the principal originator of a combined lunatic asylum and general infirmary, erected in the suburbs of Philadelphia in 1755 and 1756 and designated the Pennsylvania Hospital. The institution continued to fulfil this dual purpose until January, 1841, when all the insane were removed to a new building specially constructed for their accommodation some distance away in West Philadelphia. In the course of the next ten years the old hospital was extensively remodelled, and additions have been made at intervals up to the present day. The history of these various events is related by Dr. Morton and Dr. Woodbury in a graphic and entertaining narrative, which is in every way a model of what such a work should be. The book itself is a handsome volume of 570 pages, and contains 140 illustrations, many of which are full-page size.

New Inventions.

AN ASEPTIC SPONGE-HOLDER.

WHEN seeing my colleagues using the ordinary sponge-holders I have always been struck by the difficulty of cleaning them, and also the difficulty of removing either sponge or cotton-wool. In the sponge-holder I have had made all these difficulties are, I think, removed, and any number of sponges or swabs can be used in turn on one sponge-holder. A thread is attached to the sponge or swab, passed through the cup (A), pulled tight, and held in position by a turn round the little catch (B) shown near the handle. The sponge-holder can be used in throat, abdominal, or gynæcological work. It has been made for me in various sizes by Messrs. H. Hilliard and Son, 7, Nicolson-street, Edinburgh.

R. W. FELKIN, M.D.

A NEW SKIN-GRAFTING KNIFE.

THE accompanying plate is that of a new skin-grafting knife made for me by Messrs. Weiss and Son. It is 8 in. long in the blade, 2 in. wide, and the handle is 5 in. long. The advantages I claim for it are: 1. No force is necessary to cut the graft as the weight of the knife carries it quite easily through the skin. 2. A large graft can be cut as the blade is a long one. 3. The width of the blade allows of the graft being kept flat, with the right side up, and not curled on itself in any way. 4. The blade being flat, the edge or back of the knife can be approximated to any part of the wound, and the graft pulled directly on to the part where it is intended to place it without any fear of the graft rolling up or turning over, as so often happens with the knives used at present for this purpose. The knife has been in use now for some time, and I am much pleased with the way it works.

THE LANCET.

LONDON: SATURDAY, JULY 13, 1895.

THE recent election to the Council of the Royal College of Surgeons of England presented some remarkable features which will always render it a memorable election. The number of vacant seats—viz., five—was unusually large, and two of the vacancies had been occasioned by death, and one of these two death vacancies by the death of the President. The number of the candidates—viz., nine—for the five vacant seats was not excessive, but the candidates were distinguished by the strength of their claims on the constituency, and the very even level of those claims, thus rendering selection difficult and almost invidious, and foreshadowing that close contest which actually occurred. Another distinctive feature of the election was the first operation of an amended by-law, under which voting papers were sent to every Fellow of the College whose address was known without being previously applied for, and were made returnable up to the latest possible time on the day of election. These altered conditions ensured the participation in the election of the largest number of Fellows who have hitherto voted at the College. The number of Fellows actually voting on the 4th inst. was 681; 621 by voting papers sent by post, and 60 by voting papers handed in personally. Two of the voting papers were invalid, one by reason of the voter having employed a dash instead of a cross to indicate the candidates for whom he wished to vote. Moreover, one or two voting papers arrived at the College after the election, and even on the following day, thus affording fresh evidence, if any were needed, of the small amount of attention which the busy practitioner is able to give to collegiate interests. The fact that the voting papers would this year be distributed to every Fellow whose address was known in the office of the College introduced into the contest a greater element of uncertainty because it seemed probable that Fellows would vote for the first time who had hitherto concerned themselves little, if at all, with College politics, as shown by their previous abstention from applying for voting papers. Such Fellows might be expected to be readily amenable to solicitations on the part of enterprising candidates and their friends. Curiously enough, this element of solicitation or personal canvassing was brought into play in a manner which, however successful, must be a source of regret to all who place a high value upon the maintenance of an elevated standard of professional conduct and the preservation of professional dignity. It is bad enough when Fellows or Members of the Royal College of Physicians write letters to Fellows of the Royal College of Surgeons of England soliciting votes for a candidate for the Council of the Royal College of Surgeons of England, but it is an outrage upon the honour and dignity of the profession when ladies of title indite letters to Fellows of the College to obtain votes for their professional friend or adviser. Are we returning to the manners of one hundred years ago? and are we going to assimilate the elections at the College to the old Parliamentary elections in the days when a duchess might descend from her chariot to bestow a kiss upon a butcher to secure his vote and interest? The reasonable limits of canvassing in an election to the Council of the College can be readily stated. It is perfectly legitimate for candidates themselves to issue addresses to the Fellows defining their views on current questions. This course was pursued in the election in 1889, when considerable excitement prevailed in regard to certain claims which had been advanced by Members of the College. The example was set by the late President of the College, Mr. HULKE, and the present President, Mr. HEATH, and was followed by Mr. HOWSE, Mr. RIVINGTON, and Mr. LAWSON TAIT. It is also perfectly legitimate for any body of Fellows interested either in the promotion of certain reforms at the College or in securing representation for any local centre to send out letters to the Fellows. All these processes have the merit of publicity and ensure the interchange of opinion, which is favourable to progress and the interests of the College. Personal canvassing, however, stands on a very much lower level than political canvassing, and though, perhaps, we cannot hope to arrive at a time when it will not be indulged in, we sincerely trust that it will in future be discouraged by the Fellows of the College generally.

Looking at the issue of the election, the return of Mr. WILLETT at the head of the poll, and followed by Mr. TREVES, Mr. BUTLIN, Mr. ALFRED COOPER, and Dr. WARD COUSINS, is a result by no means unsatisfactory to THE LANCET, four out of five of the successful candidates having been on the list of candidates recommended for the support of the Fellows. We were not prepared for that remarkable exhibition of canvassing which disturbed our forecast and interfered with a more triumphant issue for the friends of reform at the College. Had Mr. ALFRED COOPER been away, we have little doubt that Mr. WILLETT, Dr. WARD COUSINS, and Mr. NORTON would have been returned in company with Mr. BUTLIN and Mr. TREVES. As it was, the name of Mr. ALFRED COOPER frequently took the place either of that of Dr. WARD COUSINS or Mr. NORTON, with the result that Dr. WARD COUSINS came in as the fifth successful candidate and Mr. NORTON stood seventh on the poll, two votes only behind the first of the unsuccessful candidates, Mr. DAVIES-COLLEY. The return of Mr. TREVES and Mr. BUTLIN is not surprising, for they were evidently the strongest surgically, and Mr. BUTLIN possessed in common with Mr. WILLETT and Mr. COOPER that very great advantage at a College election of being an *alumnus* of St. Bartholomew's Hospital. The strength of the St. Bartholomew's connexion is shown in every collegiate contest. Whenever a member of the staff of St. Bartholomew's Hospital comes forward he is successful, and now that great institution is represented on the Council by five members of its staff and by Mr. ALFRED COOPER. To the strength of St. Bartholomew's Hospital the strength of Guy's Hospital is weakness, for, notwithstanding his personal and professional claims, all the

Digitized by Google

exertions of the Fellows connected with Guy's Hospital have been unable as yet quite to carry Mr. DAVIES-COLLEY into the Council.

There is one other point which strikes us in regard to the election, and that is that there were three candidates who had seats on the Court of Examiners and not one of these has been elected to the Council. This result is entirely congenial to our own predilections; for we believe that membership of the Court of Examiners, if not entirely antagonistic to progress, acts, at least, as a sedative and sometimes as a soporific. All the five successful candidates will be free from the Circean influence of the Court of Examiners and all have exhibited liberal tendencies. Mr. WILLETT and Dr. WARD COUSINS belong to the Association of Fellows, and Mr. BUTLIN has not long severed his connexion with that body. Mr. TREVES has spoken well at the Society of Fellows and in the conference of that society with the Association of Fellows. Mr. ALFRED COOPER was in former years, we believe, favourable to reform, and as he is entirely independent we have good hope of his proving himself a useful councillor.

THE Factories and Workshops Act passed through the House of Lords in one day. The Lords adopted its provisions precisely as they left the House of Commons, and gave a hurried assent to a measure which had been much discussed in the Commons, but which they themselves had no time to amend. If the Bill were to become law this course was inevitable; any change meant delay, which would have been fatal to it passing, and its adoption in its entirety was no doubt not only the best but the only practical way of dealing with the subject. It now only awaits the Royal assent.

The Bill in several respects required amendment, but on the whole it must be regarded with satisfaction, for it contains many useful provisions, to which we may briefly refer. Considering in the first instance the sanitary provisions, we note that for the first time in English law there is a statutory definition of overcrowding. The requirement which the new Act contains is that a factory or workshop is to be deemed overcrowded if every person within it is not provided with 250 cubic feet of air space, or with 400 cubic feet during any period of overtime, and beyond this the Secretary of State may by Order prescribe a requirement of greater air space under particular circumstances. Power is given to a court of summary jurisdiction, on the complaint of an inspector that the condition of a factory or workshop causes danger to health, to prohibit its continued use until the necessary works have been executed. Both these are good provisions; but the section relating to overcrowding will, we trust, not give the impression to employers that the permissible minimum of the law is under all circumstances adequate provision. A further very necessary section requires a sanitary authority to inform the factory inspector of the proceedings taken by them on any complaint made by him as to a factory or workshop. This is a requirement of which there has been much need, for the inspector has hitherto been left in doubt as to the result of his representations, and frequent inspection has been necessary to procure information which will now be more readily obtained. Mr. ASQUITH'S determination to make the Act effective has led to the incorporation of two sections which apply to work which is given out. If the employer receives notice from an inspector that the place where the work is done is dangerous or injurious to health he is prohibited under penalty from giving out work to be done in that place. He is also liable to penalty if he knowingly allows work to be done in a dwelling-house in which any person is suffering from small-pox or scarlet fever. These provisions are good so far as they go, but it is not obvious why some other maladies are not referred to. It is now many years since CHARLES KINGSLEY wrote the story of "Alton Locke," but we should have thought that the risks of typhus fever being spread by clothing would have been in the mind of the late Home Secretary.

One of the most important provisions in the Act is contained in the twenty-ninth section, which requires the notification by medical practitioners of cases of lead, phosphorus, or arsenical poisoning or of anthrax contracted in factories or workshops. This is the first requirement of notification of chronic maladies, and experience will be required as to how it will work. As a safeguard in this respect the notice is only to be sent when the case has not been previously notified, but obviously this is a point upon which the medical practitioner may have no knowledge. Mr. ASQUITH may, however, rely upon the willingness of the profession to coöperate with him in this useful demand. The one serious objection we see to the section is that the medical officer of health is not the recipient of the notice, but the Chief Inspector of Factories. Obviously the medical officer of health, if he does his duty in a district, must concern himself with the diseases of occupation, and we regret to see any statutory provision which might seem to imply that his duties did not include the prevention of these maladies.

We observe with satisfaction that factories and workshops are to be maintained at "a reasonable temperature." The need for such a demand has no doubt been found necessary in practice, and certainly compliance with it should be insisted on. The Committee of the House of Commons to which the Bill was referred experienced some difficulty in determining whether a specified temperature of 60° F. should be prescribed in the Act, or whether the general expression which is now contained in the section should be substituted for it. Probably the wiser choice has been made, especially as the difficulty of preventing excess of heat in summer renders a specified temperature almost impossible. As the section now stands it at any rate gives opportunity for the prosecution of flagrant offenders. Among other useful provisions may be noted the requirement that every occupier of a workshop shall give notice of the address of his workshop to the factory inspector, and shall further make annually a return showing the number of persons employed by him, with particulars as to their age and sex. There are also two further new provisions of considerable importance. The first of these makes laundries subject to the Factory Acts, some modification being made as to their

Digitized by Google

application. Exception is made with respect to laundries in certain public institutions and in institutions conducted for charitable purposes. The second is the prohibition of the occupation of underground bakehouses which are not in occupation at the time of the commencement of the Act. This is obviously a somewhat crude way of dealing with the subject, but we are not disposed to take exception to it. The effect will, no doubt, eventually be not only to ensure better conditions in new bakehouses, but also to enable sanitary authorities to judge by a higher standard any underground bakehouses previously existing in their districts.

Further restrictions are imposed upon the employment on overtime of young persons and especially of women. The limitation of the hours of labour can only be enforced by successive statutes as public opinion approves the adoption of such measures, but this opinion has already decided in favour of the prevention of the overworking of women. The Act is an important advance in factory legislation, and one of its beneficial effects will be to make preceding Acts more workable. Its tendency is, no doubt, towards centralisation of the duties of supervision, but this is inevitable if its provisions are to be enforced throughout the country with more energy than those of the Public Health Act are by some local authorities.

IT has been said recently that, apart from collision and deliberate destruction by an enemy, no well-found ship should ever be lost at sea. Strength of construction and engine power have minimised danger from wind and storm; position can be gauged to a yard or so by means of charts and Lord KELVIN'S ingenious compass and sounding apparatus; lightning stroke is, or ought to be, rendered perfectly innocuous by conductors; and fire can be combated by discipline. But collision is an evil which claims a yearly tale of victims—witness the *Elbe* disaster the other day—and one which it seems very hard to avert. The subject of defective vision in connexion with accidents both at sea and on land has recently been discussed at some length in our columns, and many correspondents have written showing how commonly guards, engine-drivers, signalmen, and seamen employed on look-out duty have been found to be wofully deficient in colour sense, or acuity of vision, or both. Now, we maintain that this country is specially interested in safe locomotion, either by land or by sea, for there is more railway mileage for its size than in any other country in the world, except possibly Belgium, and we own about half the ships afloat. Wherefore, seeing that a defective look-out man is a perpetual source of danger, not only to his own ship but also to the other which he may run into, it behoves the Government to ensure that all means are taken for securing, so far as may be, that all seamen, other than firemen perhaps, should have their vision tested by a medical officer. We are far from saying that the Board of Trade does not take trouble to have the tests for colour sense and acuteness of vision applied, but we have reason to believe that the tests in question are applied by the nautical examiners and not by medical men; and we think it not unlikely that the examiners themselves, if questioned on the subject, would allow their unfitness to adjudicate upon such delicate questions of scientific medicine as refraction and Daltonism. The East Indian Railway, as a correspondent who has every right to speak tells us, have made their "medical officers responsible for the sight and colour vision of every candidate for employment who can in any way have anything to do with the working of trains or signals." If this can be managed in India, there is no reason why the same rule should not be enforced here, in the matter both of railway and shipping companies. Testing for defects of vision ought to be in the hands of experts, and we think the Board of Trade would do well if it insisted upon this being the case.

On Feb. 1st, 1895, a deputation, which included almost all the most prominent ophthalmic surgeons in this country, laid before the then President of the Board of Trade various evidence to show the supreme importance of arranging for a proper system of tests to be applied by experts to employés working on railways and in ships. Mr. BRYCE'S reply was of the stereotyped official character. He could not but acknowledge the great weight and influence of the deputation, but he could assure them that the Board of Trade was fully alive to the importance of the matter, that it had only limited statutory powers, that candidates for the posts of master mariner and mate were tested, that they had no statutory powers with regard to railway officials, and so on. Now this sort of answer is not enough; the importance of the matter warrants our urging in the strongest manner that measures should be taken to assimilate British testing examinations, as far as thoroughness goes, to those which are held in India. If the new Ministers wish to lead off with a thoroughly necessary measure of reform—one, moreover, which touches the interests of every class without interfering with the privileges of any—let them consider and act upon our suggestions.

HE must be a very casual and superficial student of the history of the profession who has not noticed the conspicuous and important part that is played at the present time by societies which exist for the defence and protection of the profession, and especially of its individual members. No profession is more in need of such societies than our own. It has no recognised representation in Parliament as the other two great professions have. Its members in the very course and nature of their duties are exposed to misrepresentation and attack as the other professions are not. Neither is there any body within the profession, constituted by law, for protecting and guarding the reputation and the interests of its members. There are, indeed, medical bodies, so-called medical authorities, as specified and set forth in the Medical Acts, which pose as the *alma mater* of their respective members; but these act rather as a stepmother than a real one, and display little interest in their children after the latter have once paid for their degrees or diplomas. Even the General Medical Council, which has some powers of punishment, has no power of protection and is slow to exercise its powers of discipline over those practitioners who by disgraceful professional conduct

Digitized by Google

injure the profession and bring discredit on its members. Such members would remain unnamed and unpunished were it not for the action of such societies as the Medical Defence Union (Limited) and the London and Counties Medical Protection Society (Limited). When it is considered that these societies are purely voluntary associations, having no legal status, and that they have only existed for a few years, it is cause for wonder that they have done so much for the profession. It is not easy to see how the General Medical Council would be able to fulfil its functions without them or some such association.

It may be argued that the General Medical Council should be armed with the power and with the duty of taking the initiative in bringing to judgment those who violate the traditions and the unwritten and written laws of the profession. This is a question that merits attention at the hands of those who seek to promote amendments of the Medical Acts. Be this as it may, we are for the present dependent on the two societies which we have mentioned for watchfulness in the detection of defects or faults in medical conduct and for any attempt to bring them under the notice of the individual medical authorities or of the General Medical Council. The efficiency of these societies cannot, therefore, but be a matter of enormous interest to the profession. It is recognised that they have attained to a high degree of efficiency. We see them fail occasionally in their endeavours to induce the medical authorities or the General Medical Council to remove from the Register those who, according to them, have forfeited their right to a place there. But this is no proof that they have not acted rightly in submitting such cases to the judgment of the Council. Their powers of investigating facts are limited as are their means of doing so. When this limitation is considered the wonder is that they have done so much as they have. They have made themselves felt as a terror to evil-doers, and they have given a new sense of security to every honest and honourable practitioner within their membership. It is difficult to say which of these associations has deserved best of the profession or has the claim to be preferred. Each is represented by a president, who stands on a professional eminence which commands universal respect and who has little personally to gain by his office. There is, in fact, no other criticism to make concerning these associations save that at present there are two of them, we will not say acting in rivalry, and most certainly not acting in opposition to each other, but by their duality weakening the defensive power of the profession which, united, would be irresistible.

It is not easy for outsiders to understand all the influences which have led to this division. Some time since it seemed possible to hope that it was to be healed; but the hope was not then realised. An honest and earnest and we trust successful attempt has just been made to bring about this most desirable consummation, and the proceedings at the meeting will be found reported in another column. It is intelligible that there are difficulties still in the way which need frank expression. There should be no raw haste: let them be fairly considered. But we would impress on the executive of both associations that unity is strength, and that there never was a time when the interests and the very reputation of the profession made it more necessary for unity and strength to exist in its counsels. It seems sanguine to expect the British Medical Association to undertake such work as that done by the Medical Defence Union and the London and Counties Medical Protection Society. It is otherwise employed, and, intentionally or not, it has allowed this function to pass into other hands. The function is a grave and lofty one, and calls for the help of members of the profession of experience, of judgment, and of honour, with a disposition to keep practitioners with a little tendency to err, in right lines rather than to accuse them. Out of these two associations it should be possible to construct an executive which would answer to all these qualities, and we have no doubt that the amalgamation will soon be *un fait accompli*. The two societies will gain the gratitude of the profession by earnestly studying the conditions of a just and sound amalgamation which will provide each practitioner with a refuge from unmerited malice and detraction and a protection against unjust and unprofessional competition. We feel very keenly that enormous benefit will be secured by amalgamation, and, as will be seen from a letter which was read to the meeting on Wednesday, and which is published in another column, we have endeavoured to lend a helping hand towards such a desirable result.

Annotations.

"Ne quid nimis."

EXPERIMENTS ON LIVING ANIMALS.

IN the return made to the House of Commons "showing the number of experiments performed on living animals during the year 1894, under licences granted under the Act 39 and 40 Vict., c. 77," some most interesting and instructive features are brought out. It is evident that the greatest care is taken (*a*) as to the qualifications of the holders of the licences, (*b*) as to the places for which licences are granted for the carrying on of experiments, and (*c*) as to the complete organisation of the system, and inspection of these licensed premises. Dr. Poore's return gives the following information. The total number of licensees during the year 1894 was 185, of whom 56 performed no experiments, and 129 performed 3104 experiments. Of these experiments 1054 were physiological, 1602 pathological, and 448 therapeutical. These figures suggest a somewhat too artificial division which, however, is not borne out on reference to the details of the elaborate tables given, as many of the experiments classified as physiological and pathological should really come under the heading of therapeutical, though they should come there only through the direct bearing they have on therapeutics. It is of importance to bear this point in mind in dealing with these statistics. Under the licence alone 942 experiments, and under Certificate C. 128 experiments were performed; and in these cases the animals can suffer no pain or discomfort even, as complete anæsthesia is maintained from before the commencement of the experiment until the animal is killed. Under certificates A, A and E, and A and F 1549 hypodermic injection or inoculation experiments which involve no more pain than is given by the prick of a needle were made. Under certificates B and B and E E 495 experiments were performed, and, as the inspector points out, these animals were all anæsthetised during the performance of the operation, but were then allowed to

Digitized by Google

recover. "These operations," he says, "in order to ensure success, are necessarily done with as much care as are similar operations upon the human subject, and the wounds being dressed antiseptically no pain results during the healing process." That careful supervision is exercised and that the law is carried out most strictly is abundantly evident from the report. A full list of the "licensed places" is given. "All licenses were restricted to the licensed place or places specified on their licenses, with the exception of these who were permitted to perform inoculation experiments in places other than a 'licensed place,' with the object of studying outbreaks of disease amongst animals in remote districts." It is certainly evident, then, from a study of the report that all experimental work has been conducted in suitable places; that licenses and certificates have been granted and allowed only upon the recommendation of persons of high scientific standing; and that the licensees are persons who, by their training and education, are fitted to undertake experimental work and to profit by it. Dr. Poore and Sir James Russell have reported on all these points, and the result is a most interesting document—especially interesting from the point of view of those who, whilst approving of facilities being granted for the carrying out of necessary experiments on living animals, are anxious to be satisfied that these experiments are carried on under careful independent supervision. From Ireland Sir Thornley Stoker has much the same to report, except that here the number of experiments made was exceedingly small. Only nine experiments were performed, and these were all of a painless nature, "and were directed to useful ends. Eight of them were investigations of the effects of bacterial poisons, and one an examination of the secreting power of the kidney."

APPOINTMENT OF POLICE SURGEONS: A NEW DEPARTURE.

IT will be remembered that early in the year a deputation from the United Kingdom Police Surgeons' Association waited upon Mr. Asquith with suggestions on four points. Two of these were the desirability of appointing special police surgeons in those districts which at present have none, and the importance of issuing to all provincial police surgeons the instructions furnished for some time past to the metropolitan police surgeons as to the examination of prisoners charged with criminal assaults on females. It is gratifying to see that the efforts of the deputation have borne fruit. From the *Surrey Advertiser* we learn that a committee of the Surrey county council recently had before them a circular letter of the Secretary of State pointing out the advantages to be derived from the appointment of recognised police surgeons to examine prisoners arrested on certain charges; and the committee were of opinion that it was desirable such appointments should be made. They had therefore selected certain medical practitioners residing in the various districts of the county to act as police surgeons in the cases referred to at a reasonable fee, not exceeding one guinea for each case. We certainly hope it will not be less. In Taylor's Medical Jurisprudence it is laid down that "in all these cases there should be good medical evidence and a corroboration from circumstances." We trust that the gentlemen appointed to perform these important duties will be experienced practitioners duly impressed with the very serious nature of their duties and fully competent to perform them. While, on the one hand, it is imperative that no man should be convicted of so serious a charge unless it be fully brought home to him, it is no less imperative that when the charge is fully proved by medical and other evidence a conviction should follow. That some females are ready to prefer false charges against innocent men is too true, but it is no less true that there is a vile class of male offenders for whom a long term of imprisonment is the only proper punishment. Skilled medical evidence is required in all these cases, as well for the innocent as for the guilty.

THE RECENT PROSECUTION OF AN UNQUALIFIED ASSISTANT.

AT Southwark Police Court, before Mr. Kennedy, Mr. Francis Morny Coppin was prosecuted by Mr. Braxton Hicks for giving false certificates. There were six summonses in all. Mr. Braxton Hicks began by drawing attention to the fact that Mr. Coppin was an unqualified man and that his employer had been already dealt with by the General Medical Council. He added that on certain technical grounds five out of the six summonses would be withdrawn. He would now proceed to the first case, that of Harriet Bates. This certificate stated: "I last saw her alive on Feb. 17th, 1895, and she died on Feb. 18th, 1895," and the certificate was dated Feb. 19th, and signed G. F. McCarthy. Now the last day that Mr. McCarthy saw the patient was the 13th, and on the 19th he was at Brighton. Mr. Coppin, when the representatives of the child came for the certificate, filled it up, signing Mr. McCarthy's name. He (Mr. Coppin) would plead guilty in this case. Mr. Braxton Hicks went on to point out how, if an unqualified man was at liberty to represent or to use the name of a qualified man, much crime might be hidden. Mr. Braxton Hicks having mentioned the facts, said he wished to withdraw all the summonses except the first, in the case of Bates, and Mr. Coppin was fined £10 and 2*s.* costs. Mr. Braxton Hicks deserves the warmest thanks of every right-thinking person for his conduct of this case. Actions like that of Mr. McCarthy and Mr. Coppin are fraught with danger. The power to give a death certificate is one which ought to be guarded in the most jealous manner, and any methods which go to show that this power is abused are most reprehensible. Mr. McCarthy has been dealt with by the General Medical Council, but we would wish him to bear in mind the legal maxim, "Qui facit per alium facit per se."

A PROSECUTION UNDER THE INFECTIOUS DISEASES NOTIFICATION ACT.

AT the Edmonton bench, on July 4th, Dr. Benjafield, the medical officer to the Strand Union Schools, was fined 10*s.* and costs for not "forthwith" notifying a case of infectious disease in one of the school children. The London and Counties' Medical Protection Society, represented by Mr. Stone, defended Dr. Benjafield. It appears that a case of scarlet fever was diagnosed on June 8th, and the case was ordered to be removed. But the 9th being a Sunday, the information was not received by the Metropolitan Asylums Board in time to send their ambulance until the 10th. The medical officer of health of Edmonton saw the ambulance and followed it to the school on the 10th, and it was only then that the superintendent of the school wrote out a form of notification; but the medical officer's certificate, even if posted on the 13th, was not received till the 14th. A delay between the 8th and 13th cannot be regarded as compliance with the terms of the Act; the more so as no defence as to uncertainty of diagnosis in this case was maintained. If the Act is to be useful, the notification should, apart from reasonable cause being shown to the contrary, be despatched on the day when, or at latest the day after, the medical practitioner becomes aware of the existence of the infectious disease. We do not know how far the difficulty which arose in this case has been due to any objection to notify, lest there should be interference on the part of a medical officer of health in an institution which

Digitized by Google

is under the medical charge of a special officer. This has arisen in workhouses and other places. But these establishments come within the provisions of the Act as to notification, and no attempts should be made to avoid compliance with its terms. The ordinary courtesies of the medical profession should suffice to avoid needless action and interference of health officers in cases where a special medical officer is responsible for the administration of a public institution. Mr. Stone contended that when every precaution had been taken to prevent the spread of the disease, and the authorities had been made duly cognisant of its occurrence, the whole spirit of the Act had been complied with. The bench, however, were of opinion that the letter of the law had not been complied with and inflicted the small penalty on Dr. Benjafield. Although not wholly successful in their ministrations (and, as will be seen from what we have already said, we do not think it possible for the magistrates to have come to any other decision), we consider that the society were actuated by quite the right sort of motive in taking up the case. Any prosecutions under this most useful but most ticklish Act which have the appearance of being vexatious are greatly to be deplored as being calculated to interfere with the proper working of the regulations.

MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ON the 4th inst. and on the following day an exhibition was held in the council room at the Royal College of Surgeons of England of all the specimens added to the museum during the past year. The additions have been very numerous, and include many of great interest. Among the pathological specimens may be mentioned the following. A case of sarcoma of the patella, which was shown at the Pathological Society by Mr. D'Arcy Power. A case of sarcoma arising in the subscapularis muscle and invading the chest wall; an attempt was made to remove the growth, but the patient died. Two specimens showing trophic changes in the lower limb in locomotor ataxy. A roll of human hair weighing five pounds, removed successfully from the stomach of a woman who had been in the habit of biting and swallowing her hair; there were no signs of insanity in the patient. A vermiform appendix about nine inches in length. A secondary carcinoma growing from the transverse portion of the arch of the aorta of a dog, causing pressure on the trachea with dyspnœa. A recurrent carcinoma of the breast in a man who had had a similar growth removed from the same situation ten years previously. Several specimens of old injuries to the beaks of birds, resulting in much deformity from the unequal growth of the beaks. In the teratological series two specimens were worth noting. One was a fœtus with an additional arm and leg on the left side, and also an additional left kidney. The other was a field vole (Arvicola agrestis) with absence of the hind limbs and the posterior region of the body. Several specimens illustrating diseases of the liver and gall-bladder which accompanied the Jacksonian Prize Essay for 1894. A humerus removed from an Egyptian tomb of a date about 4000 B.C. showed an old injury to the head of the bone, resulting in much deformity. Several excellent dissections have been added to the department of normal human anatomy; they chiefly refer to the muscles and ligaments of the foot. There are some admirable dissections of the nervous system of animals; and many dissections to show endo-skeletal structures, and among them may be mentioned the cartilaginous skeleton of the lamprey (Petromyzon fluviatilis) and of Raia maculata. Two hundred and five skulls were purchased from the Anthropological Society, and among them were the skulls of many races not previously represented in the collection. Several examples were shown of the assumption of male plumage by old female birds; the specimens include golden pheasants and Japanese pheasants. No satisfactory explanation of this change has been given.

INQUESTS WITHOUT MEDICAL EVIDENCE.

A REMARKABLE and flagrant instance of a policeman being permitted to give medical evidence at an inquest is published in the *Somerset County Gazette* of June 22nd. The body of a woman having been found in the Bridgwater Canal near Fordgate, Somersetshire, the police sergeant at North Petherton is reported to have stated, among other evidence: "The body was very rigid, the hands were clenched, and there was a frothy mucus round the mouth and nostril, which are indications of death from drowning. I had the body conveyed to her residence, where I had all the clothes removed and made an external examination of the body. I found no bruises or signs of violence whatever." Comment on this case is superfluous. There is at least one medical man in the district, and the circumstances, if correctly reported, appear even more indefensible than any of the inquests without medical evidence recently recorded in THE LANCET.

SWEET ARE THE USES OF ADVERTISEMENT.

WE have received a pamphlet containing a "list of names of some of the medical men who have sent testimonials (unsolicited) in favour of ——'s extract." Thackeray once wrote a paper of suggestions to a young novelist for bringing in the names of various firms, which firms would then supply the writer with assorted articles mentioned; but we do not think it becoming to see medical men's names and addresses prominent in a commercial advertisement, although in many cases we can hardly credit the letters being written by educated men. The varying styles of testimonials would form a valuable nucleus for a "complete commercial letter-writer." Here, for instance, is the simple straightforward, business-like style:—

25th September, 1885.

Mr. —— begs to enclose P.O.O. (£1 3s. 6d.). It is a most valuable restorative. Send two gallons directed as before.

——, M.R.C.S.

Two gallons of Post Office Orders would be a valuable restorative to many persons! Next comes the Joseph Surface or extreme courtesy style:—

15th May, 1884.

Gentlemen,—I am enabled to speak commendably of your "Extract ——," which you so kindly sent me. I have found it a most agreeable stomachic, and for pleasantness to the palate is certainly most inviting. My recommendation to many has, I hope, been productive of gain to you, as well as a very pleasing duty on my part.

Ever your obliged and grateful servant,

——, L.R.C.S.

In contrast to this is the involved third-person style:—

March 13th, 1885.

Doctor —— will feel obliged by Messrs. —— sending one dozen pints of their "——" to —— railway station. Dr. —— has used a small portion of the Extract in cases of diarrhœa with extreme debility, and with marked success. Dr. —— feels satisfied that when its efficacy in various affections becomes more generally known in this locality that it will be largely availed of, seeing that it combines the many excellent qualities of therapeutic and diatetic (*sic*) with rapidity and cheapness. Amount will be forwarded on receipt.

"Diarrhœa with extreme debility, and with marked success," is, we suppose, a synonym for cholera. And what are "the qualities of therapeutic and diatetic"? Lastly, we have the pathetic:—

Sunday, 12th October, 1884.

Gentlemen,—I have tried your sample bottle of "——" with a very urgent and chronic case of asthma and heart disease in a gentleman sixty-seven years of age. I am now with my patient, and he has found comfort and support from the —— when champagne, brandy and milk, and turtle soup fail. Send me a pint through post as quick as possible, or a little more of it will come through post.

Case extremely urgent. Will fear no delay. I materially doubt the issue of this illness, being ten years suffering, but wish to try your remedy. I will send you cheque or P.O.O. immediately I hear from you I am, Gentlemen, yours faithfully,

——— M.D., L.R.C.P.

This appeal would melt the heart of a stone. Picture the anxious physician sitting at the bedside. Champagne,

Digitized by Google

brandy and milk, and turtle soup have all failed. But Messrs. ——'s extract, the veritable ambrosia, arrives, and all is well. Seriously, though, is it fitting that this sort of puffery should go on unchecked? The compound in question, we daresay, is nutritious enough, but the pamphlet seems to advertise the testimonial-writer as much as the preparation.

THE WORTHING WATER-SUPPLY.

IT is now some time since the yield from the well which has been sunk at great cost by the Worthing corporation on the South Downs equalled the million gallons per day which were required by the Local Government Board before application for pecuniary help would be sanctioned. This week the undertaking of the West Worthing Waterworks and Baths Company has been handed over to the council, which is now, therefore, in possession of the water supply of the whole borough. By a majority of one the council has decided to adopt the system of private loans as against corporation stock to cover the expenses of a trying term.

PROPOSED MEMORIAL TO PROFESSOR HUXLEY.

IT has been decided to establish in connexion with the Charing-cross Hospital Medical School a permanent memorial to one of its most distinguished students, the late Professor Huxley. To this end the following committee has been formed: Sir Joseph Fayrer, K.C.S.I., F.R.S.; Sir Guyer Hunter, K.C.M.G. (both old friends and fellow students of Professor Huxley at the Charing-cross School); Dr. Watt Black (honorary treasurer), Mr. J. H. Morgan, Mr. Stanley Boyd, Dr. Montague Murray, and Mr. H. F. Waterhouse (honorary secretary). It is proposed that the memorial shall take the form of an annual lecture and a science scholarship and medal; but the final decision will depend upon the wishes of a general meeting of the subscribers. A meeting will be held at Charing-cross Medical School on Tuesday, July 16th, at 3 P.M., Sir Joseph Fayrer in the chair, to further the establishment of the memorial. It is hoped that all former students of the school and others interested in the memorial will attend. Subscriptions will be received and acknowledged by Dr. Watt Black at the Charing-cross Hospital Medical School.

SUMMER SCHOOL OF MEDICINE AT CAMBRIDGE.

THE "Summer School of Medicine for qualified practitioners" held in Cambridge during last week was a signal success. Eighty members were present from all parts of the country, this being about as many as could conveniently and without crowding be accommodated at the demonstrations in the laboratories and in the hospital. They were provided with rooms, dinners, and breakfasts in King's and Downing Colleges; and they were most enthusiastic in their praises and thanks for all that was done for them. They, with one accord, said that they had never passed so agreeable and instructive a week. Each day was fully occupied, and they were most diligent in availing themselves of the opportunities offered. The only complaint made was that they would gladly have paid more than the sum charged, which was barely sufficient to cover the expenses of board and lodging in the Colleges. The meeting was opened on Monday evening by an address from Sir George Humphry, which was published in the last issue of THE LANCET. Lectures were given by Professors Allbutt, Foster, Humphry, and MacAlister, Dr. Anningson, and Mr. Douty; demonstrations in the laboratories (physiological) by Dr. Shore and others, (pathological) by Dr. Kanthack and Dr. Lazarus-Barlow, and (therapeutical) by Mr. Marshall; also demonstrations of patients at the hospital by Professor Bradbury, Dr. Laurence Humphry, Mr. Wherry, Mr. Deighton, and Dr. Griffiths. A remarkable exhibition of beautiful drawings of ophthalmoscopic views of the retinæ of various animals, including the lion, tiger, rhinoceros, &c., taken by Dr. G. Lindsay Johnson, who has long been working at this subject and is preparing a book on it with illustrations, and shown by him, was very attractive. The whole programme was carried out in such a manner as to be decidedly encouraging to a repetition of the same in any future year in which the several professors and others concerned may be willing to undertake the trouble of offering a similar boon to the medical men of the country. At the conclusion of a smoking-concert on Friday evening a pair of handsome silver candlesticks was presented to Dr. Griffiths by the visitors as a wedding-gift and as a token of their appreciation of, and obligation for, the pains he had taken to ensure their comfort and to organise and promote the success of the meeting.

A SERIES OF COMPLAINTS.

AT the last meeting of the Petersfield (Hants) board of guardians the Local Government Board Inspector (Mr. Baldwyn Fleming) made a series of remarkable complaints. At the dead-house that morning he had discovered a woman in her coffin with the shroud unfastened. In the infirmary he had seen a paralytic patient who had "been allowed to lie in bed under such conditions as to almost cause bedsores." There were two people in the house who had been married forty years. The man was paralysed and bedridden; the woman eighty-two years of age, blind and unable to walk. They had only met four times in the last six months; the inspector thought they should be together at least once a week. Mr. Fleming objected to the lying-in ward as inconvenient in every way and altogether inadequate. Lastly, he objected to the proposed amalgamation of two relief districts in view of the recent recommendations of the Aged Poor Commission. If the board pressed the latter they must take the responsibility. He told them plainly he did not like it and could not agree with their views. A certain amount of suspicion is apt to be raised by five grave grumbles in one day. There may have been carelessness in the first two cases; the inspector may have been correctly informed by the aged couple whose cause he espoused; the lying-in ward may be useless as such; and the proposal of the board may be unwise. It is certainly a case, however, in which the other version ought to be heard before judgment is pronounced. The inspector's report is very sweeping in its ubiquitous fault-finding.

THE SELECT COMMITTEE ON FOOD PRODUCTS ADULTERATION.

IT is now fifteen months since a Select Committee was appointed to inquire into the working of the Margarine Act, 1887, and the Sale of Food and Drugs Act, 1875, to report whether any, and if so what, amendments of the law relating to adulteration were in their opinion desirable. On the close of the Parliamentary session on Aug. 1st last the committee reported that it was not in their power to conclude their inquiry, and the evidence taken up to that time was published in a Blue-book which was dealt with in THE LANCET of Oct. 20th. It embodied the evidence of witnesses who consisted chiefly of, firstly, Government officials and then wholesale dealers. Comparatively bulky as this Blue-book was, we ventured to think it could not contain but a tithe of the complete hearing. Since then a number of witnesses have been examined who are likely to afford valuable evidence from the public analyst's point of view. Not the least interesting aspect to ourselves of this important section of the inquiry will be the opinions expressed by these gentlemen on the question of standards, of samples for

Digitized by Google

reference, and of the manner of the purchase of samples. With these points we propose to deal on a future occasion as soon as the minutes of evidence are published. The labours of the committee are by no means finished, and, as we predicted, the inquiry has become more arduous and more prolonged than was probably anticipated. On the 2nd inst. the Committee met to receive the draught report of the chairman, which was to the effect that further evidence upon the matters referred to them had been taken, but that they have not had sufficient time to conclude their investigations. This is practically the same conclusion as was reported at the end of the previous session. They therefore agreed to report to the House the evidence already taken and to recommend that a committee on the same subject should be appointed in the next Parliament. The coming general election may therefore have an important bearing on the constitution of the new committee next session, since a change of administration will of course lead to the appointment of many new members.

SELF-POISONING BY CHLOROFORM.

FEW practices are at once more pernicious and more common than auto-intoxication by means of chloroform. Within a few days two persons have done themselves to death by inhaling chloroform. Mr. F. C. Banks, as a result of a poisoned wound inflicted by pricking his finger with a toothpick, suffered great pain. It appears from the evidence of his wife that he inhaled chloroform to obtain relief. It is almost incredible that this man had for eighteen months received regularly daily at his house two ounces of chloroform for auto-intoxication. He poured a small quantity upon a paper cone and inhaled it. The wife awakened to find the unfortunate man comatose and stertorous, and from this state he never recovered. It seems to us perfectly monstrous that the victim should ever have had the chloroform supplied to him. The laity know so little of the perils of inhaling anæsthetics that they ought at least to be protected from themselves and others equally incompetent to administer the drug. In the second case, a young surgeon, Mr. T. G. Sloan of West Calder, suffering from neuralgia and sciatica, inhaled chloroform to secure sleep and forgetfulness of his pains. While comatose he appears to have fallen forward and so inhaled a lethal dose and died. Thus two lives are sacrificed to a reckless use of one of the most beneficent drugs given to man to assuage those ills to which flesh is heir.

PLATO AND THE PHYSICIANS.

IN a curious passage in one of the most famous of his dialogues—the Phædrus—Plato sketches his view of the doctrine of the transmigration of souls. The soul which has seen most of truth in its former state comes to the birth as a philosopher, or artist, or musician, or lover; that which has seen truth in the second degree shall be a righteous king, or warrior, or lord; the soul which is of the third class shall be a politician, or economist, or trader; the fourth shall be a lover of gymnastic toils or a physician; the fifth a prophet or hierophant; to the sixth a poet or imitator will be appropriate; to the seventh the life of an artisan or husbandman; to the eighth that of a sophist or demagogue; to the ninth that of a tyrant. "All these," says the philosopher, "are states of probation, in which he who lives righteously improves, and he who lives unrighteously deteriorates his lot." The order of precedence in the above list is very curious and highly characteristic of the Hellenic mind. The philosopher at the top of the scale and the tyrant at the bottom show that even Plato was not free from the prejudices of his nation and his caste. The place he assigns to the physician—viz., fourth in the scale—is not a very elevated one, and it is somewhat singular to find him bracketed with the lover of gymnastic toils. It is something, however, to find that the "prophet or hierophant"—the ancient representative of an important profession—is placed even lower—viz., fifth. Plato's comparatively low esteem for the profession of medicine is not difficult to understand, since at a time when anatomy consisted of a few crude facts and physiology did not exist, it was impossible that medicine could command the reverence of any profound and penetrating intellect. We find Plato constantly in his dialogues alluding to medicine as if it consisted of little else but giving a purge or an emetic. No doubt Hippocrates was a man of profound genius and of immense knowledge, considering his time, but it is very unlikely that the average practitioner rose above the level of the mere drug-giving empiric. Lovers of Plato, who, we trust, are not few in the profession, may read their favourite author without feeling aggrieved that in his appreciation of medicine he did not rise above the level of his time. It is probable that the average practitioner of those days combined much presumption and not a little chicanery with a "plentiful lack" of real medical knowledge, and it can hardly be a matter of wonder that the philosopher looked askance upon such pretenders.

THE RESTORATION OF ST. MARY OVERIE.

WE have received an appeal from the restoration committee of the ancient Church of St. Mary Overie, better known as St. Saviour's, Southwark. This church, so well known and studied by travellers on the South-Eastern Railway owing to the kindness and thoughtfulness of the S.E.R. Company in not infrequently stopping their trains between London Bridge and Cannon-street just opposite to it, is, after Westminster Abbey, the finest example of mediæval architecture remaining in London. It was anciently served by the Augustinian canons regular, a religious order to which medical men owe much, for in their hands, too, was the great Hospital of St. Bartholomew. £8000 are urgently required, and we earnestly hope that the complete restoration of a building so interesting historically, and which after its long slumber may again be a centre of good works, may not be delayed for want of money. Subscriptions may be sent to the Bishop of Rochester, the Bishop of Southwark, to the treasurers, Sir Frederick Wigan and Mr. Robert Barclay, or to the Rector of St. Saviour's, Southwark, S.E., or to Mr. James F. Field, lay honorary secretary, 54, Borough High-street, S.E.

"THE EVICTION OF MR. T. M. WATT."

IN our issue of June 22nd last we commented, under this heading, severely upon the action of Sir William Worsley of Hovingham towards his tenant, Mr. T. M. Watt, basing our strictures upon a statement laid before us by Mr. Watt and upon an uncontradicted report of the circumstances of the eviction which appeared in a lay contemporary of more than local importance—the *Leeds Mercury*. Owing to communications we have since received from Sir William Worsley's solicitors and from residents in the neighbourhood of Hovingham, we see reasons to modify the opinions then expressed; while we feel that, whatever our sentiments in the matter might have been—altered or unaltered—it would have been our duty, and in accordance with the impartiality with which we have ever striven to discuss disputes between medical and lay citizens, to give to our readers Sir William Worsley's side of the matter, having expressed ourselves upon Mr. Watt's version. First, then, Mr. Watt's statement (which he supplied to us in pamphlet form) that it was his attempt to secure a better sanitary environment for the people of the neighbourhood which had placed him in opposition to the great man of the place is absolutely traversed

Digitized by Google

by Messrs. Hugh W. & R. Pearson, Sir William Worsley's solicitors. They find it to have "no foundation in fact" and to be "absolutely ridiculous." Secondly, the suggestion that Mr. Watt has been driven from Hovingham under circumstances "from which no single element of hardship would seem to be absent"—an opinion of ours based upon Mr. Watt's words to us that his landlord had so far as in him lay confiscated the practice, and so deprived Mr. Watt of his livelihood, without entertaining the question of arbitration concerning compensation—is flatly contradicted by Messrs. Pearson, who write that Sir William Worsley "has repeatedly, beginning in 1886 (long before the Local Government Act and the elections under it to which Mr. Watt and the *Leeds Mercury* ascribe the notice to quit), offered to purchase Mr. Watt's practice on the usual terms, and ..... these offers were renewed down to the time that ejectment proceedings had to be taken." Thirdly (and this is a matter of far less moment) it would appear that our interpretation of the views of the neighbourhood cannot be maintained. The large number of names appended to a petition asking Sir William Worsley to reconsider his decision led us to the inference that the majority of Mr. Watt's fellow residents were in sympathy with him. But we have since received communications from sources beyond reproach that Mr. Watt did certainly bring upon himself his own misfortunes, and that he did this in such a manner that even those who sympathise strongly with him—in which category more than one of our correspondents may be classed—hold Sir William Worsley void of reproach in the matter. We have reflected upon Sir William Worsley's conduct in a manner which the facts now brought before us show us to have been undeserved, and we desire to place this on record in reparation before closing our columns to all discussion of the topic.

THE DIFFUSION OF SMALL-POX.

MATTERS have not tended to improve during recent weeks in London as regards the prevalence of small-pox, the cases newly arising in the four weeks ended Saturday, June 29th, having been 5, 6, and 8, with a further considerable increase to 24 attacks, and a single registered death from the disease—namely, in an unvaccinated adult aged between twenty and forty years. The deceased belonged to the St. Giles sanitary area. The malady is thus seen to be on the increase in the metropolis, the patients remaining under treatment at the close of the last three weeks of June having risen from 19 to 22, and again to 34. Near at hand the borough of Bedford continues to suffer to a slight extent, though the disease makes no headway despite its presence in small amount. In the Midlands, Derby is still the chief centre of small-pox prevalence, though there the malady is dying out apparently, the cases having been only 2 or 3 in each of the last two weeks of June, as compared with more than 12 in the preceding week, but the deaths registered were 3 in the early part of the month. At Hayfield the guardians have had some little to-do on account of the presence of small-pox in their workhouse, and have been much exercised as to the best course to pursue in connexion with the feared spread of the disease by means of tramps, especially in view of the recent experience of Derby and New Mills in the matter of tramp-carried small-pox. There have been 5 cases in the house, including 1 fatal attack in a male adult. At Liverpool a death over a fortnight ago has been followed by one or two cases in and around the city, and Manchester has had a few cases in the past month, districts of the city previously free from the disease having been invaded, but every care has been taken to promptly isolate the infected persons. One case has occurred at Salford and some attacks are chronicled at Wigan, whilst at Oldham two deaths have been recorded in the last month, and the fresh cases have increased of late, until in the last fortnight of June there were a score of attacks heard of in the borough. But energetic measures are being adopted with a view of combating the disease. Small-pox wanes slowly in Dublin, where, in the two weeks ended June 22nd, the admissions to hospital were 13 and 11 respectively, with 9 and 13 discharges; 6 deaths were registered in the period, 4 in vaccinated adults aged over twenty years, and 2 in unvaccinated children under five years of age. The acute cases of the disease remaining under treatment on the 1st of the month numbered 41, and on the 22nd they were 31, besides 17 convalescents at Kilmainham. Sir Charles Cameron, the health officer of the city, fears that the disease will not die out before the winter recrudescence sets in.

THE POST OF PATHOLOGIST TO THE LONDON COUNTY COUNCIL.

DR. FREDERICK W. MOTT was elected on Wednesday last to the post of Pathologist to the London County Council. In securing the services of Dr. Mott, who, after a most distinguished career at University College, became assistant physician to Charing-cross Hospital and lecturer on physiology at the Medical School, we congratulate the Council upon choosing a man of wide practical knowledge of medicine and proved ability in the direction both of original work and scientific literature. Dr. Thomas D. Savill was, we understand, a close second to Dr. Mott, while Dr. W. Lloyd Andriezen, the pathologist and assistant medical officer to the West Riding Asylum at Wakefield, was also on the selected list.

AN OLD STORY.

"IT has been suggested that the facts are sufficiently remarkable and mysterious to make it worth while stating a case for THE LANCET." Such are the closing words of a newspaper cutting dated May 6th. We have waited patiently for the case to be stated, but so far it has not reached us, and all we can gather from the somewhat meagre materials to hand is that someone thought he vomited some wasps or bees which he imagined he had swallowed in the shape of one insect full of ova last summer. Of course the whole story is quite impossible. To begin with, we doubt the possibility of swallowing a live bee or wasp—dead ones, of course, would not be difficult—but either dead or alive they would soon be partially digested, and the idea of wasp or bee grubs hatching in the stomach is too ridiculous. The tale is only a variant of that which exists in all countries of people who have swallowed newts, earth worms, fish, frogs, &c. when little and which have grown to vast proportions and given rise to most distressing symptoms. Readers of Max Adeler may remember his delightful story of the man who swallowed the frog, which sat in his stomach and said "Blood an' oun" in a sepulchral voice at inopportune moments; but this kind of thing does not occur in real life.

THE EXTENSION OF EPSOM COLLEGE.

ON Monday, July 8th, His Royal Highness the Prince of Wales laid the foundation stone of the new Lower School at Epsom College. This extension has for long been desired by the Council, and by an Act of Parliament obtained last year the Council were enabled to open the school to all classes, special privileges being reserved for the children of medical men. We are glad to think that the boys will, since the passing of this Act, number representatives of all occupations and professions, for to live perpetually in an atmosphere, so to speak, of only one interest tends to narrowness, and we all know that the essence of education at a public school is not the mere book learning, but the self-government arrived at by intercourse with one's fellows—the learning

Digitized by Google

that individual interests must be subordinated to those of the whole body, and the *esprit de corps* which remains throughout after life. There is no body of men, perhaps, who deserve a place where their children can be taught and nurtured at a low cost more than medical men. They are very hardly worked, and they share with ecclesiastics the proud feeling of knowing that the more zealously and thoroughly they carry out their work, by so much the more they limit their opportunities for work. Many of both professions fall by the way; for the sons of the clergy there are already plenty of helpful institutions, but for those of medical men there is but one, and for this reason we are glad to see its foundations strengthened and its scope enlarged. We would impress upon members of the medical profession and upon those indebted to them that the present occasion is a fitting opportunity to afford the College that support without which its function, both as a great benevolent society and also as an educational institution, must be seriously impaired.

THE CENTRAL AUTHORITY AND A HEALTH OFFICER'S SALARY.

THE Millom urban council have decided to reduce the salary of their medical officer of health, and the Local Government Board have urged them not only to reconsider their decision, but they have suggested that the appointment should be made for a longer period than one year. The Millom authority then explained the reasons for the reduction, which reasons the Local Government Board declare to be inadequate. The Millom people now reveal their hand; they answer that if the post were advertised—which, by-the-bye, ought already to have been done—"there are other efficient medical gentlemen in the town who ..... would doubtless compete against the present medical officer." It is to be hoped that the Local Government Board will refuse to sanction half payment of the salary out of county funds if this attitude on the part of the Millom council is maintained; but it is infinitely more to be hoped that the medical profession will stand firm against the suggestion that they will underbid a colleague who, as the central authority declare, is by no means overpaid. A united front against such local action and a refutation of the calumny involved in the resolution of the local council are wanted in this instance.

THE VESICATING CONSTITUENT OF CROTON OIL.

IN a communication made to the Royal Society, Mr. Wyndham R. Dunstan, M.A., F.R.S., and Miss L. E. Boole, Lecturer on Chemistry in the London School of Medicine for Women, record the results of an experimental inquiry into the nature of the vesicating constituent of croton oil. According to the research of Buchheim, and more recently of Kobert and Hirscheydt, the vesicating action of croton oil is due to an acid closely allied to oleic acid, which has been given the name of crotonoleic acid, and which is now prepared for medical purposes on a large scale in Germany. The process consists, broadly, in the formation first of barium crotonoleate, and the subsequent decomposition of this with dilute sulphuric acid, and extraction of the liberated crotonoleic acid as a viscid oil with ether. By a process of fractional precipitation, using lead salts, the above investigators were able to separate from this so-called crotonoleic acid a large proportion of inactive oily acids, till at last they were successful in obtaining, by a series of operations in which alcoholic extraction and separation by means of lead oxide were made use of, a resinous substance having extraordinary power as a vesicant. The composition of this resin is expressed by the empirical formula $C_{13}H_{18}O_4$. All attempts to crystallise or to obtain crystalline derivatives failed. It is a hard, pale-yellow, brittle resin, nearly insoluble in water, light petroleum, and benzene, but readily dissolved in alcohol, ether, and chloroform. In regard to its constitution it is concluded that the vesicating constituent of croton oil is a lactone or an anhydride of complicated structure.

CAMBRIDGE MEDICAL GRADUATES' CLUB.

THE annual dinner of this club was held at 8 P.M. on July 4th at the Hotel Victoria, Northumberland Avenue, under the chairmanship of Sir G. M. Humphry, M.D., F.R.S., the president of the club. The Rev. Canon W. Page Roberts, Mr. Oliver Pemberton of Birmingham, and Mr. T. Pridgin Teale, F.R.S., of Leeds, were the guests of the club. The Chairman gave the toasts of "The Queen" and "The Club," Dr. Norman Moore proposed "The Health of the Guests," and Professor C. S. Sherrington, F.R.S., gave the toast of "The Chairman."

THE PHOTOGRAPHING OF PATIENTS.

AT a recent meeting of the guardians of St. George's-in-the-East the Rev. L. S. Wainwright complained that the medical officer of the infirmary had photographed a female patient of weak intellect in a nude state, and that thereby the friends of the patient were much incensed. The medical officer explained: (1) that he took the photograph in the interests of science, the woman having a peculiar malformation; (2) that the patient was not mentally deficient; and (3) that she was suitably attired and the matron or a nurse was present. A resolution was then passed to the effect that the medical officer should be instructed not to photograph any person thought to be of weak intellect without obtaining the consent of the board. At a meeting held on June 28th it was proposed to rescind the resolution, but the motion was lost. If the reports submitted to us be correct, a great deal of fuss seems to have been made about nothing. In the case of persons of weak intellect it would seem advisable to throw the responsibility of deciding whether they should be photographed or not upon the relatives or persons interested in the patient, and not upon the board. Boards should never have any responsibility laid upon them; however able the individual members may be, a board as a board is generally a useless body. Of course, no photograph of any patient should ever be published without the consent of the patient or the patient's representative; but we fail to see why a photograph should not be taken.

THE FUNERAL OF MR. HUXLEY.

THE very funeral of a great man has a peculiar interest of its own. This was peculiarly true of Huxley's. The place—which might have been Westminster Abbey—was the pleasant and rural cemetery for Marylebone at Finchley, looking beautiful, as even cemeteries do in July. The company was not numerous, but it was highly distinguished, including men representing all branches of science and learning. The Royal Society was personified in Lord Kelvin, the President; Professor Michael Foster, the secretary; and Sir John Evans, the treasurer. There were present, too, Mr. Lecky, Sir J. D. Hooker, the Rev. Dr. Dallinger, Professor Ray Lankester, and Dr. E. Frankland. The medical profession was not unrepresented, though the Presidents of the Royal Colleges of Physicians and Surgeons, respectively, were unable to be present. Sir James Paget, accompanied by Miss Paget, was there; also Sir Joseph Lister, Dr. Lauder Brunton, Mr. Henry Power, Dr. Burney Yeo, Dr. Felix Semon, Dr. Glover, and others. It was noticed that many working men were present. It was gratifying to see the great Agnostic buried with all the amenities of

Digitized by Google

Christian burial. One humble man asked if the ground was consecrated ground. The reply was that it was so, and the feeling of the reverent mourners was that henceforth it would be more consecrated than before. The service was read with much simple force by the Rev. John Llewelyn Davies, now Rector of Kirkby Lonsdale, formerly Vicar of Christ Church, Marylebone. Never was the momentous fifteenth chapter of the first epistle to the Corinthians read with more acceptance than over the great apostle of science who was more religious than he would admit or, perhaps, knew, and who, it is said, wished, a few days before his death, to be buried with the service of the Church of England. We scarcely regard this wish as one of the inconsistencies of a great man. Like other great men, with all the boldness of his thought, he knew the sharp limitation of his own knowledge. No deep student of his philosophy can charge him with irreverence or fail to see in his writing the conception that there is in the universe a Being whose "intelligence was as far beyond his own as that was beyond a blackbeetle's," "endowed with powers of influencing the course of nature as much greater than his as his is greater than a snail's."

CEREBRAL HÆMORRHAGE IN PURPURA HÆMORRHAGICA.

DR. NEWGARDEN of the United States army records in a recent number of the Philadelphia *Medical News* the case of a Swede aged thirty-eight who first sought advice on account of persistent oozing of blood from the cavity from which the second right upper molar had been removed on the previous day. Under appropriate treatment the bleeding ceased, and there was no recurrence in the few days during which he was kept under observation. A few weeks later, however, he again sought advice on account of weakness in the legs, and he stated that there were some spots on the skin. Examination revealed the existence of a number of large purpuric spots scattered over the legs from the ankles to the middle of the thighs. They underwent the usual changes and were rapidly disappearing when he one day complained of severe headache, became convulsed, lost the use of the left side, and passed into a comatose condition. Consciousness returned in an hour, but he soon lapsed into his former condition, and died four days after the initial headache and convulsion. During the few days that elapsed before his death there was incontinence and hæmaturia. At the necropsy it was found that the left ventricle was greatly dilated, with vegetations on both aortic and mitral valves, the latter being bound down by adhesions. The right ventricle was dilated, and the kidneys granular and cystic. A large hæmorrhagic extravasation was found over the right cerebral hemisphere, and there was also a clot in the middle lobe from rupture of a branch of the middle cerebral artery. The case is a curious one, and it might be suggested that the symptoms were the result of the cardiac and vascular conditions secondary to granular kidney, and not of the real but mysterious disease known as purpura hæmorrhagica.

THE testimonial to Sir Joseph Lister, to be given to him by his former colleagues and pupils on the occasion of his retirement from the active staff of King's College Hospital, will be presented to him at the Hospital on Tuesday, July 30th, at 4 P.M. The presentation will be made by Sir John Eric Erichsen, and in order that the necessary arrangements may be made Dr. J. Fredk. W. Silk, the honorary secretary of the undertaking, will be glad to hear from gentlemen intending to be present.

THE profession has heard with pleasure of the Knighthoods conferred upon Dr. Thornley Stoker, the President of the Royal College of Surgeons in Ireland, and Dr. Christopher Nixon, the Physician in Ordinary to the Viceregal household.

REPORT OF THE COMMITTEE ON PRISONS.

V.[1]

THE Committee deal at some length with the subject of the "nine months' separate confinement of convicts." This is ever a favourite topic for criticism when our prison system comes under consideration, and it was not likely to escape the scrutiny of the Committee.

"In the consideration of several matters contained in the reference we had to touch upon the practice of confining convicts for nine months' solitary imprisonment either in local or convict prisons. Objection was taken by some witnesses to the presence of these men in local prisons, though others specified that no special difficulty was thereby caused. As, however, the practice establishes in certain local prisons, which are the collecting centres for convicts, a class of men who have to be kept distinct from other prisoners, and who require special individual treatment, we felt it necessary to investigate the reasons for the practice. The history of it is interesting and suggestive. It was organised in 1842 by Sir James Graham, then Home Secretary." At this time, we are told, Pentonville Prison was designed on new and approved ideas for the reception of convicts sentenced to transportation, and was to be restricted generally to those who were convicted of their first offence and whose age was between eighteen and thirty-five. It was to be a prison of instruction and probation; the convict was to undergo eighteen months' solitary imprisonment, but he was to be freely visited by the chaplain and prison officials; he was to be trained in a productive industry; he was to be subjected to a progressive system of education on the class system; lectures were to be given to him in the prison chapel; he was to be kept in a state of cheerfulness; hope, energy, resolution, and virtue were to be imparted to him, and he was to be trained to be fully competent to earn his own way and become a respectable member in the penal settlements. If during the eighteen months he behaved well, he would at once receive a ticket of leave on arriving in Van Diemen's Land. It would have been sad indeed to its promoters if such a programme had proved a failure. Whatever may have been its permanent effect on the convicts in the penal settlements, we are told that the plan was worked apparently with great success so far as home treatment was concerned. The Commissioners for Pentonville thus report in 1844: "The effects produced on the minds and conduct of the prisoners by this system of separate confinement have been highly satisfactory." And they thus describe the general results: "Most satisfactory proofs of these beneficial impressions have been manifested in the great improvement which has taken place in the moral condition and conduct of the prisoners within a short period of their reception. In the course of our visits to the cells we have had the gratification of witnessing to a great extent their just appreciation of, and the deep interest which they take in, the moral and religious instruction which is imparted to them; the removal of the debasing effects produced on their minds by their former criminal pursuits; their progress in self-improvement; their cheerful obedience to the prison rules; their acquirements in the trades which have been allotted to them; and their gratitude for the treatment they have received under a discipline which combines instruction and reform." If we could bring ourselves to accept this eulogium as a fair criticism and not merely as a pæan of hope and trust, we would say "happy convict," and regret that only convicts had such a moral and religious opportunity. But it was too good to last and "in 1848 it was determined that, eighteen months being too long a period for isolated confinement, a system should be introduced based on a period of separate confinement, followed by a term of associated labour, with a maximum of twelve months. This was reduced by Lord Palmerston in 1853 to nine months." Our Committee go on to say that the original intention of Sir James Graham, which was that this period should be primarily of a reformatory character,

[1] Parts I., II., III., and IV. were published in THE LANCET of May 4th, 18th, 25th, and June 15th respectively.

Digitized by Google

appears fifteen years later to have been lost sight of. "It would appear," they add, "from Sir Joshua Jebb's evidence in 1863 that the main object of separate confinement had come to be deterrence." "An educated prisoner," he said, "would much prefer separate confinement instead of being driven to associate with people of bad character and difference in social position. With burglars and reckless bad characters, I think that separate confinement is dreaded more than any other kind of discipline." The Royal Commission of 1863 insisted on the necessity of enforcing the full nine months, and they proceed to say, "we think, too, that though separate confinement, even under the present system, is, as has been said, extremely distasteful to convicts, this wholesome effect on their mind might be increased. ..... There appears to us to be much force in the reasons which induced the directors of Irish convict prisons to adopt these means (lower diet, monotonous work, and less frequent visits) for rendering separate imprisonment more formidable, and we, therefore, recommend that attempts should be made, with due caution, to give a more deterrent character to separate imprisonment in the English prisons." From this it is to be gathered that there were reasons for looking upon the results of Sir James Graham's scheme as not being an unmitigated success. Our Committee say that the passage quoted "shows that Sir J. Graham's intention and scheme had perished, and that the period of imprisonment originally designed to train and improve prisoners for a good and useful life was now looked upon and intended to be the most formidable and coercive part of the punishment of penal servitude. In effect this is the purpose which it must be regarded as now designed to serve. It must, however, be admitted that the evidence seems to show that the Commissioners and the officials of the prisons have not either a complete knowledge of the history of the matter or a very clear idea of its working and effect. It is certainly a practical convenience in the sense that the expense of sending convicts immediately after sentence to convict prisons, either singly or in small detachments, is curtailed by the system of gathering prisons. This consideration alone is not sufficient to justify the practice. The argument that it is a necessary discipline for penal servitude, if true, is no argument for sending the convicts to local prisons. We do not regard the system with favour. We see no objection to short periods of detention in local prisons for the purpose of collecting parties for transfer to the convict prisons, but if the system is a good one at all we think it ought, so far as possible, to be worked out in convict prisons from first to last. We think that it cannot be denied that cases occur in which a nervous condition, agitated by remorse and by a long continuance of the separate system, may be injuriously affected by it. From the evidence before us we have no reason to believe that such cases are of other than exceptional occurrence. We think it is worth considering whether the severity of the system might not be mitigated by a substantial reduction in the period of separation and by the wise and carefully guarded introduction of such reformatory influences as were brought to bear on convicts at Pentonville when first established, and of such philanthropic agencies as appear to be engaged in behalf of separated convicts in the Belgian prisons." We have quoted the words of the Committee in full, lest, on a subject to which they naturally attach some importance, we should run the risk of mutilating their views. It is, to say the least, unfortunate that the Committee in various parts of their report do not restrict themselves to the use of the term "separate" in regard to the phase of prison life under consideration, because the idea of "isolation" which they introduce in the terms "isolated confinement" and "isolated imprisonment" has no place in connexion with the English prison system, and the use of the phrases is apt to mislead the uninitiated. We should have been glad if the Committee, in the expression of opinion which we have quoted above, had made it more clear to the ordinary reader that they were dealing with two totally different questions. It is a vital question as regards any prison system whether a period of "separate confinement" is or is not desirable; but it is quite unimportant, except as a matter of administration, whether that separate confinement is carried out in a convict or in a local prison. The Graham scheme of separate confinement has admittedly "perished"; but we are not informed whether it was departed from because it failed (latterly), or whether it failed because it was departed from (as to its conditions). The Committee are disposed to proclaim the ignorance of the Commissioners (we suppose they include the directors of convict prisons) and the officials of the prisons in this matter; but we are bound to say they do not attempt to clear it up themselves, and we should be glad to see the evidence upon which they base their assumption. We have already quoted the views held by the Commissioners of 1863 on this subject, and the Penal Servitude Acts Commission of 1879 state that "it has been suggested by some witnesses that the period of separate confinement which precedes removal to public works might be prolonged with advantage; but the limitation of the period to nine months is the result of much experience, and although the period might possibly be extended to twelve months without mental or physical injury to the majority of prisoners, we do not see any sufficient reason for disturbing the present regulation." Coming to more recent times, in their report for the year 1887-8 the directors of convict prisons deal with this very subject, while in Appendix No. 19 to that report is published a most valuable memorandum on separate confinement by the Medical Inspector of Prisons. If the Committee will take an opportunity of reading what is there stated they will find that neither the history of the subject nor its working and effect have been overlooked by officials of prisons who are responsible in the matter. In the beginning of his memorandum the medical inspector says: "The term 'separate confinement,' though convenient as a technical term by which to indicate a particular kind of prison discipline and management, is apt to convey to persons not familiar with the subject an erroneous impression of the circumstances under which a prisoner is placed either when undergoing a term of imprisonment in a local prison or when passing through the 'probation stage' of a sentence of penal servitude. He is not separated from his fellow creatures. On the contrary, he sees and hears as much of them as do many persons at liberty; quite enough to prevent the growth of any sense of isolation from the rest of mankind. The visits of the various officers, instructors, and schoolmasters are sometimes so frequent as to occasion discomfort, and I have no doubt that many prisoners would like to be left rather more to themselves. The prisoner of the present day is well cared for; he is supplied with all the necessaries, and not a few of the comforts, of life; and his existence is, to say the least, rendered very endurable." He concludes his remarks in the following terms: "I trust that I have succeeded in showing that the apprehensions formerly entertained as to the effects of separate confinement were groundless, and that it is as compatible with a healthy state of body and mind as any other form of imprisonment."

We await with interest the long-delayed publication of the evidence given before the Committee because at the present moment we are not satisfied that there exist any well-established grounds for "mitigating by a substantial reduction in the period of separation" what the Committee refer to as the "severity of the system."

OCULISTS' SEALS.

THE valuable articles which have from time to time appeared in the *Révue Archéologique* from the pen of le Capitaine Espérandieu upon Roman Oculists' Seals have now been gathered together and published in the form of a book.[1] This corpus of all the known oculists' seals, although modestly alluded to by the author as "a not useless work until another performs it better," is really an admirable specimen of what a monograph upon such a subject should be, and indicates prolonged and careful research in reference not only to the seals themselves, but to the many statements in classical authors upon medicine bearing on the matter. It is peculiarly complete because of the arrangement in a series of tabular forms of the whole of the seals; then of the collyria mentioned upon them; followed by another series giving every ocular disease mentioned upon the seals, together with the one or more collyria stated to have been effectual for their remedy; then a list of every collyrium is given with all the diseases each is said to have been curative of. These tables are all elaborately furnished with cross references, and the second one giving the list of collyria on the

[1] Recueil des Cachets d'Oculistes Romains. Par le Capitaine Émile Espérandieu. Paris: Leroux.

Digitized by Google

stamps is rendered immensely more valuable by being supplied with citations from the chief medical writers of antiquity, and also a list giving the name of the place where an oculist seal bearing the name of the collyrium has been found. In addition to these tables Captain Espérandieu also supplies an alphabetical list of all the oculists' names, and a chronological one of dates of discovery of the seals, commencing with 1606 and citing the authority for the texts engraved upon them. As is well known, these seals when found in perfect preservation usually bear the name of the oculist, manufacturer, or vendor, of the collyrium they were used to impress, then the name of the medicament itself, followed by instructions as to its usage, and sometimes indications for its mode of employment. The writer's diligence enables him to give about 200 seal inscriptions enumerating 149 different collyria and approximately eighty various titles for diseases of the visual organs.

One of the most interesting portions of the subject is the series of remedies and their constituents, and to this question the writer has devoted a great deal of attention. In one case we are enabled to have an absolute chemical analysis of several collyria. This is in the instance of those belonging to C. Firmius Severus, whose case of instruments and about 40 grammes of his collyria were found at Reims in 1854. The latter were analysed by M. Duguenelle, but apparently not separately according to their stamps. They contained organic matter, silica, peroxide of iron, black oxide of copper, oxide of lead, and carbonate of lime. It might naturally be supposed that the titles of the collyria, together with the names of the one or more diseases they were remedial of, and the references to them in ancient medical treatises, would certainly enable us to form a fairly correct idea of their various ingredients; but this frequently is not the case, for the necessary evidence fails. Nearly all the names are of Greek derivation only four or five at most being of Latin origin. Many of them manifestly are indicative of their manufacture, especially those commencing with the preposition διά, such as diaceros, or diacislas (of ivy), or diasmyrnes (from myrrh). Others merely supply the Greek word for the chief remedial ingredient, such as arpaston, amber; crocodes, saffron; stactum, oil of myrrh. But, on the other hand, many titles afford no clue to the substances referred to, such as hyginon, salutary; diatessarium, the fourfold ingredients; and the following names, which are plainly derived merely from a eulogistic encomium of the properties of the material, as with some more modern preparations. Ambrosium, basilium, isochrysum, theochristum, theodotium, speak eloquently of their divine or regal origin; whilst simpler titles, such as chloron or cirron, allude merely to their colour.

M. de Mely, in an essay upon the subject some years ago, pointed out that in nearly a score of cases the appellatives are derivatives of the names of stones, such as the amethyst, sapphire, and turquoise; but these titles again are, doubtless, used merely to further impress upon the vulgar the extreme value of the preparations, and are not to be taken literally as the name of their actual constituents. The most important contents of the work are the maladies set forth in the list with explanations of their true meaning, as far as possible derived from classical medicine, each furnished with a full mention of all the collyria said to be designed for their cure. For instance, to the term "ad caliginem"—that is, obscurity of vision—no less than eleven names of collyria are given, but not satisfied with these, derived solely from the inscriptions, Captain Espérandieu refers us, giving chapter and verse, to Celsus, Paulus Egina, Dioscorides, Scribonius, Nicolas Myrepsus, Ætius, Galen, Actuarius, Marcellus, and Pliny for further knowledge.[2] For "ad lippitudinem," or ophthalmia, there are a score of remedies, and we are referred to Actuarius, Galen, Celsus, Ætius, and others. Among the remedies are dialibanum, or incense; spodiacum, or metallic fragments; amber, myrrh, and nard. The following may be given as a specimen of the inscriptions upon the stamps, because this one evidently belonged to a specialist on ophthalmia; it was found at Naix, in the department of the Meuse, and is now in the Louvre:—"Junii Tauri theodotium ad omnem lippitudinem: Junii Tauri anthermerum ad epiphoras et omnem lippitudinem: Junii Tauri penicille molle ad omnem lippitudinem: Junii Tauri diasmyrnes post impetum lippitudinis." Another seal of Junius Taurus has been found, and also four belonging to a Quintus Junius Taurus. Of all remedies myrrh and oil of myrrh seem to have been held in highest esteem, if we are justified in forming a definite conclusion from the 200 seals at present exhumed.

Our space will not permit of further notice of this interesting volume, as with all well-got-up modern works it is supplied with a bibliography of the subject, and also a list of ancient "oculists" mentioned in lapidary inscriptions other than their seals; and, finally, there is a supplement containing six new signets discovered in 1893–94, to which the publisher appends four blank pages, so that the student can fill in fresh ones as they come to light. Enough has, perhaps, been said to induce our readers to turn to the work for themselves; it is to be had for less than 10 francs, and will prove a welcome addition to the library of any medical man who desires, in his, perhaps, too rare moments of leisure, to ascertain something of the antiquarian history of his profession.

[2] Much information may be derived when the "Dynameron" of Elius Promotus is published. From a table of its contents preserved in a manuscript in the Escurial we are told that Chapters 92 to 107 are devoted to eye diseases, 96, 97, and 106, 107, and 108 being specially concerned with collyres, and Chapter 98 with liniments.—See Annuaire des Études Grecques.

THE MEDICAL DEFENCE UNION (LIMITED) AND THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY (LIMITED).

ON Wednesday, July 10th, the conjoint councils of the above organisations for the defence of the medical profession assembled at 20, Hanover-square, to consider the question of amalgamating the two bodies. Previously to the commencement of the meeting it was, we understand, decided that reporters should not be admitted, but on Mr. Hutchinson being voted to the chair the question was discussed, and on the motion of Dr. Purcell, seconded by Dr. Bridgwater, a resolution was put and carried deciding that members of the press should be admitted.

The Chairman then read the following letter which had been addressed to him by the Proprietors and Editors of THE LANCET:—

July 10th, 1895.

DEAR SIR,—In our position as Editors of THE LANCET we have never failed to be impressed with the urgent and crying need which exists for the foundation on a firm and assured basis of a really representative society devoted to the defence and protection of the interests of the whole medical profession. Various efforts have been made from time to time in this direction in the past, but until recent years they have been attended with little permanent success.

The establishment of the Medical Defence Union and later of the London and Counties Medical Protection Society has shown that with good organisation and management excellent results can be secured, but it appears to us to be an anomalous, unfortunate, and unnecessary circumstance that two different bodies, between which there must unavoidably be a certain amount of rivalry, should exist. No real good can be achieved without solidarity, cohesion, and practical unanimity.

We understand that at the meeting to-day the question of the possibility of fusion of the two societies will be seriously entertained. As a practical, and we hope helpful, token of our anxiety that this much to be desired result may be attained we shall be happy *on the completion of the amalgamation* of the Medical Defence Union and the London and Counties Medical Protection Society into one body to hand to the treasurer or treasurers of the newly-formed union or society or association a cheque for 100 guineas, and to place the columns of THE LANCET at the reasonable disposal of the union or society or association in whatever way may be mutually found to be most convenient and best calculated to promote the truest interests of the profession as regards the defence and protection of its individual members.

We are, dear Sir, yours faithfully,
(Signed.) THOMAS WAKLEY,
THOMAS WAKLEY, Jun.,
Editors of THE LANCET.

To the Chairman of the Meeting of the Councils of the Medical Defence Union and the London and Counties Medical Protection Society.

In explaining the object of the meeting Mr. Hutchinson said the members of the councils of each society had been summoned to an open conference to discuss the desirability and practicability of amalgamation. He suggested that the best method of conducting the business would be to move a simple resolution to the effect that these two societies should be amalgamated.

Mr. Victor Horsley moved, and Dr. Heron seconded, the following resolution, which was carried: "That in the opinion of this meeting it is most desirable that the amalgamation of the London and Counties Medical Protection

Digitized by Google

Society and the Medical Defence Union should forthwith be carried out."

Dr. Heron, in the hope of avoiding much discussion which might not altogether tend to smooth the way of amalgamation, proposed that their difficulties in the condition in which they at present stood should be referred to arbitration. He proposed that the legal advisers of the Medical Defence Union and of the London and Counties Protection Society should cause to be drawn up for submission to counsel and other competent persons a joint case, stating in a way fair to both societies the legal difficulties which beset their amalgamation, and also a joint requisition that counsel and other competent persons should advise the two societies as to the method best calculated to help their amalgamation in the way which would best secure the true interest of all concerned, with special regard to finance, dispatch, and reasonable economy of expense. He did not think that much good could result from this meeting discussing the history of the negotiations that had passed between the delegates of the two societies since 1893, but he thought that great and speedy good would come from the adoption of the principle of the proposal he had just made. He had purposely somewhat vaguely stated that the difficulties should be submitted to "counsel and other competent persons" because he did not wish to suggest to the meeting more than the lines on which they might run with comfort. By "competent persons" he meant men chosen by each society who would meet counsel specially skilled in company law, and so form a board to which their difficulties might be submitted. Personally, he thought it would be a wise thing if these men were made plenipotentiaries, and whatever decision they arrived at followed out loyally. All his council were in favour of amalgamation, but they wished to have an assurance that every step would be taken with the due observance of the safety of all, the saving of money, and expedition.

Dr. Alderson seconded the motion.

Mr. Victor Horsley was extremely unwilling to appear in this discussion in any degree in the sense of opposition to any reasonable proposition that might be laid before them, and no one could contend that they had not had a reasonable proposition, but he earnestly desired to see amalgamation carried out as speedily as possible, and he should very much regret the loss of time if this meeting came to an end without coming to a definite conclusion on the subject.

A long discussion then followed on the power of the meeting to vote, and on the question of certain details upon which the opinions of the lawyers, Mr. Hempson, Mr. Oakley, and Mr. Eustace Smith, were taken.

Mr. George Brown wished to substitute for Dr. Heron's resolution a similar one in simpler words, but Dr. Heron did not feel inclined to accept this. His resolution was again read to the meeting.

Mr. Stamford Felce thought they had advanced a stage since Dr. Heron proposed his motion.

Dr. Heron thought that the proposition would only cause matters to end in a deadlock.

Eventually Mr. Bruce Clarke suggested that two delegates from each society with legal advisers be appointed, with power to consult Mr. Buckley if necessary, to draw up a scheme to be laid before an adjourned meeting of the conjoint councils. This was agreed to, and a vote of thanks to the chairman terminated the proceedings.

On the motion of Mr. Hutchinson, seconded by Mr. Victor Horsley, thanks were returned to the Messrs. Wakley for their interest in the meeting and for their kind offer.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

MONDAY, July 8th, 1895, the occasion of the laying of the foundation-stone of the New Lower School buildings by His Royal Highness the Prince of Wales, will be rubricated in the annals of Epsom College. All Epsom seemed to take an interest in the event, and although the decorations cannot be described as profuse there could be no doubt that the inhabitants had done their best to do honour to the occasion. From Epsom Town Station, where a guard of honour of the East Surrey Volunteers received their Royal Highnesses the Prince and Princess of Wales shortly after 3 o'clock, along Church-street to the College, flags fluttered on either side. Banners bearing words of welcome to the Royal party were suspended along the route, and festoons of bunting decorated many of the houses. When the Royal party arrived at the College they were received by a guard of honour of the College Cadet Corps, and, accompanied by the President of the College, his Grace the Duke of Abercorn, and the Duchess, they were conducted to the dais by the Reception Committee, consisting of Sir Joseph Fayrer (chairman of the council), the Rev. Edward W. Northey (vice chairman), Dr. Constantine Holman (the treasurer), Mr. George C. Croft, Mr. Lumsden Propert, Mr. Lawrence, Mr. H. Vardon, Dr. Needham, Sir Arthur Watson, Q.C., and Colonel Gordon Watson. The Headmaster, the Rev. T. N. Hart Smith, was then introduced to His Royal Highness by Sir Joseph Fayrer, and Miss Alice Hart Smith, the Headmaster's little daughter, presented a bouquet of flowers to the Princess, which she received with her accustomed grace. At this stage of the proceedings the marquee in which the ceremony was performed presented an imposing spectacle. The glorious weather had tempted the ladies to put on their brightest attire, and the gay dresses, the decorations of bunting and flowers, blending with the cool of the evergreens, which, fanned by the soft breeze that pervaded the marquee, gracefully waved to and fro, the silent sea of interested faces—all this presented to the eye in the light of the sunshine subdued by the yellow and crimson striped awning a scene which is not likely to be soon forgotten by those who witnessed it.

After his introduction to the Prince the Headmaster read an address to His Royal Highness on behalf of the staff of the College, in which he tendered to the Prince their most respectful and hearty thanks for graciously consenting to lay the foundation-stone of the new Lower School and expressed the very great pleasure they felt in welcoming the Princess also on this occasion. Referring to the founder of the institution, John Propert, Mr. Hart Smith said his (the founder's) desire was to confer a lasting benefit on the medical profession by providing the means of best assisting their orphans and widows, and by founding a school where their sons might receive a first-rate education at as low a cost as possible; and with this end in view he appealed hopefully and boldly to the public at large to testify by their assistance of the scheme the gratitude they must ever feel to a body of men who gladly face many dangers and too frequently have their lives cut short in ministering to others God's merciful gifts of healing. These objects had been steadily kept in view, and after encountering periods both of sunshine and of gloom they were able this day to point with thankfulness to the firmly established position of Epsom College. The school had now for some years been quite full, and 250 boys, the sons of medical men and others with them, were being educated within its walls. Its scholars had succeeded in entering with credit the medical as well as other professions, and they had distinguished themselves by winning many open scholarships at the universities and at the London hospitals. No less than fifty boys were educated on the foundation, free of all cost, and in various ways, by means of scholarships and exhibitions; many others received assistance. The Council had recently been enabled to increase to £30 the yearly grants made to non-resident pensioners. The course of education given is similar to that in other public schools, and while fitted, especially in the direction of science teaching, to meet the wants of boys preparing for a medical career, it sought to impart to all classes of boys a healthy and liberal training, both mental and physical. The enlargement of the school on a free and wide basis had long been desired, and the new Act obtained by the Council last year had opened it definitely to all classes alike, while giving special privileges to the sons of medical men. It was now intended to place in this new building 100 of the younger boys, who will thus, in accordance with modern ideas, be separated from the main body of the school. Other necessary works were also in progress, foremost among them being the enlargement of the school chapel.

The Prince of Wales, in reply to the address, said: "I am very much obliged to Mr. Hart Smith for the address which we have just heard, and assure him and you and all who take an interest in the welfare of Epsom College the pleasure it gives to the Princess and myself to be present to-day and take part in this interesting ceremony. The account given of the school shows it to be in a prospering condition, and most

Digitized by Google

sincerely do I hope that it will ever continue so. For myself, I take a great interest in it, because forty years ago I was here with my father, who was unable previously to lay the foundation stone at the opening of the College. I am glad on this occasion to be able to lay the foundation stone of this Lower School, which will increase the College and, I hope, in every sense its usefulness."

The Venerable Robinson Thornton, D.D., Archdeacon of Middlesex, the first headmaster of the College, then asked the blessing of God on the laying of the foundation stone, and Mr. J. Lumsden Propert, son of the founder of the College, handed His Royal Highness the coins of the current year, with a copy of the *Times* newspaper and an illuminated scroll, which the Prince deposited underneath the stone. Sir Joseph Fayrer handed the silver trowel to the Prince, who proceeded to lay the stone, assistance being rendered by the architects (Sir A. W. Blomfield, A.R.A., and Sons), by the Clerk of the Works (Mr. J. R. Harding, A.I.C.E.), and by the builder (Mr. J. Dorey). The ceremony was brought to a conclusion by the singing of the "Old Hundredth" Psalm, and (in the unavoidable absence of the Bishop of Winchester, the Visitor of the College, owing to ill-health) the Lord's Prayer was recited and the Benediction pronounced by the Venerable J. H. Sapte, Archdeacon of Surrey and Rector of Cranleigh.

The band of the Artists' Corps Rifle Volunteers, by the kind permission of the Colonel commanding, Robert W. Edis, T.D, F.S.A., was in attendance and rendered a good programme.

The Prince and Princess having visited the College library, their Royal Highnesses and suite left amidst a volley of cheers by the South gate and drove to the Epsom Downs Station, where a guard of honour was again formed by the East Surrey Volunteers.

The trowel with which the ceremony was performed was constructed of silver with an ivory handle and bore the following inscription: "Presented to His Royal Highness the Prince of Wales on the occasion of his laying the Foundation Stone of the New Lower School, Royal Medical Benevolent College, Epsom. July 8th, 1895."

The Royal Medical Benevolent College was first projected in 1851 by the late John Propert; the buildings at Epsom were commenced in July, 1853; and on June 25th, 1855, the College was formally opened by H.R.R. the late Prince Consort, accompanied by H.R.H. the Prince of Wales. Since then large additions have been made from time to time, and they now provide ample accommodation for over 200 boys, besides those who occupy the Headmaster's boarding-house. The new Act obtained by the Council last year definitely opened the school to all classes, and it was decided to build a lower school.

The new buildings consist of a new complete school for 100 boys; an addition to the present chapel at the east end, which is to form the commencement of an entirely new chapel to replace the present one. The new school buildings consist of a master's house, including bedrooms and sitting-rooms for five unmarried masters and a common dining-room, six dormitories, five classrooms, and all other necessary accommodation. The building will be warmed by the induction of fresh air warmed by hot-water coils, the foul air being extracted by ventilating shafts. Red brick is being used in the construction of the buildings, with Bath stone quoins and dressings. The roofs will be covered with permanent green slates. Messrs. Dorey and Co. of Brentford are the builders, and Mr. Harding of Epsom is clerk of the works. The total cost of the new school will be £12,320, that of the addition to the chapel being £2525. Sir Arthur Bloomfield, A.R.A., and Sons are the architects.

INAUGURATION OF NEW SANITARY WORKS AT PARIS.

(FROM A SPECIAL CORRESPONDENT.)

THE Congress organised by the Society of Sanitary Architects and Engineers of France was preceded by the inauguration of the aqueduct and the irrigation fields of Achères. At ten o'clock in the morning on July 7th the members of the Congress had assembled on the new iron bridge which crosses the Seine from Colombes, on the peninsula of Gennevilliers, where the first sewage farm was established, to Argenteuil. Under the carriage-way of the bridge are four large iron pipes, which receive the sewage raised by the pumps of Colombes. Here there are engines of 1200 horse-power that raise 2 cubic metres of sewage per second from the altitude of 24 metres to a point at Argenteuil at an altitude of 60 metres. From this elevation the sewage will be able to reach by gravitation the most distant irrigation fields. On the bridge a handsome verandah had been erected, with a platform underneath. The chair was occupied by M. Poubelle, Prefect of the Seine; and by his side were M. Baudin, Vice-President of the Paris Municipal Council, and representatives from the Ministers of the Interior, Public Works, and Agriculture. M. Poubelle delivered a very eloquent speech, giving a retrospect of the sanitary works accomplished. He explained that the Paris main sewers threw into the Seine 391,000 cubic metres of sewage per day, or 143,000,000 cubic metres per annum, containing per annum about 10,000,000 kilogrammes of nitrogenous substances which might be estimated at about 20,000,000 francs. Thus £800,000 worth of fertilising agents are lost annually. Three generations of engineers had sought to prevent this waste—Belgrand, Alphand, Mille, Couché, and Durand-Claye, the latter being "the sincere and persuasive advocate of the principle now accepted: 'all to the sewer and nothing to the river.' In 1900 the peoples of the world who would come to Paris to pacifically celebrate the advent of a new century will be able to admire and marvel at the perfect health the French capital would then enjoy. They will study the harmonious working of its organisation and will see in its innumerable canalisations the realisation for towns of the principles of the circulation of the blood in the human body. Like arteries reaching the utmost extremities, so will pure spring water be brought by pipes to every house and every tenement. Then from every dwelling, drain-pipes and sewers, like veins, will bring the sewage to be revivified in the pores of the earth, and by the action of the plants which will derive their nutriment from the impurities of these waters. The contemplators of this system will understand the lofty character of the lesson in natural philosophy that results from these phenomena. They will celebrate under a multiplicity of forms and appearances the grand unity of science, and they will carry away with them the conviction that the study of life and its laws can prove as beneficent for a town as for an individual, and that man is all the nearer to truth as he succeeds more and more in borrowing from nature its processes and in faithfully conforming to its laws."

M. Baudin spoke of the desire of the Paris Municipality not to compromise the interests of the neighbouring districts, but, on the contrary, to enrich their agricultural resources. They would find that the advent of sewage in the arid plains that would now be put under cultivation would not only save the Seine from pollution, but would enrich the suburban districts. After some more speeches the members of the Congress, whose presence greatly increased the imposing appearance of this function, went to Argenteuil, where a midday banquet had been prepared. This repast was, of course, followed by the toasts suitable to the occasion. Then the members of the Congress went by train to Herblay and crossed over the Seine to the 800 hectares of the plain of Achères which are to be fructified by the Paris sewage. They were able to see the first trenches made for the reception of this sewage and to inaugurate its advent on the farm.

On the following Monday morning the work of the Congress commenced at the Palace of the Liberal Arts in the Champ de Mars. On behalf of the Minister of the Interior the sitting was presided over by M. Monod, Chief of the Sanitary Services of France, who in his opening speech paid a handsome tribute to the fifteen representatives of the British Association of Sanitary Inspectors present at the Congress. On the previous evening these gentlemen, together with the other members of the Congress, had been entertained at the Ministry of the Interior by M. Leygues, the Minister. The band of the Republican Guard discoursed sweet music in the illuminated gardens of the Ministry, alternated by singing and recitations in-doors, given by some of the most celebrated performers from the Théâtre Français and other Paris theatres.

The Congress has been organised in a very practical manner. Its official sittings are held from nine to half-past eleven each morning, and two subjects only are set down for discussion. A reporter for each subject has been appointed, and his report, generally terminating in a series of resolutions, has been printed and circulated among the members. Thus all the members know what will be discussed

Digitized by Google

and on what they will have to vote. In the afternoon the subjects of discussion are left to the initiative of private members, and then follow visits to sanitary services. Thus on Monday the Congress visited the disinfecting establishment of the Rue de Récollets. This is one of the most perfectly installed disinfecting stations in all Europe. It was fully described in THE LANCET during the course of the recent cholera epidemic. On Tuesday afternoon the Congress visited the pneumatic drainage works of the Société de Salubrité at Levallois-Perret. On Wednesday the Congress will inspect the sewers, and on Thursday the public slaughter-house.

Paris, July 9th.

THE CHANGES AND ALTERATIONS IN THE CHARTERS AND BY-LAWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND SUGGESTED BY THE ASSOCIATION OF FELLOWS.

THE deputation from the Association of Fellows which was received by a committee of the Council of the Royal College of Surgeons of England on the 10th ult. was requested to draw up a *précis* of the reasons adduced in support of their suggestions for the amendment of the charters and by-laws. This has been done, and the following is the paper which the deputation has sent in, and which is now being carefully considered by the committee of Council. Although we insert the paper with pleasure we do not wish to be considered as endorsing editorially the various suggestions of the Association of Fellows, many of them being open to criticism from our point of view.

1. That it shall be lawful for the Fellows in meeting assembled to appoint an annual committee or other committee to consider and report on subjects referred to them and to confer when necessary with the Council.

The concession of half-yearly meetings of Fellows already granted by the Council requires to be supplemented by power being given to the Fellows to appoint a standing committee. No large body of men ever meet without the capability of appointing a committee to thrash out and summarise subjects and elaborate details. Moreover, it is desirable that such a committee should be intra-mural and official, instead of the work of such a committee being left to voluntary and extra-mural associations or societies of Fellows. Such a committee would (*a*) elicit and collect the opinions of the Fellows on subjects of importance, and would (*b*) act as a medium of communication between the Fellows and the Council. The duties of the committee, therefore, would be to consider all subjects referred to them by the Council and by the Fellows at the half-yearly meetings, and to report thereon, and to confer, when necessary, with the Council. It appears to the Association that the committee could be advantageously organised as follows. The committee might consist of twenty-four Fellows, twelve of whom should be elected from the Fellows resident in the London postal district, and twelve from the Fellows in the provinces. The election of the committee should take place annually at the July meeting of the Fellows by the Fellows present at the meeting. The first committee should be elected at the next ensuing meeting of Fellows after the establishment of the committee, notice of the election having been given in the agenda of that meeting. Subsequent annual committees should be elected as follows. Each candidate should be nominated by three Fellows, such nominations to be sent in to the annual committee a month before the July meeting of the Fellows. It would be the business of the annual committee to prepare a list of candidates so nominated, and the candidates would then be balloted for at the July meeting. The twelve metropolitan Fellows and the twelve provincial Fellows with the highest number of votes respectively would be the successful candidates and constitute the annual committee for the ensuing year. Five members of the committee should form a quorum. The committee would appoint its own chairman. The meetings of the committee should be held in the common room at the College. Regular meetings of the committee should be held as often as requisite, but not less than once in three months.

2. That some change be made in the mode of election of the President of the College in accordance with the vote recently given by the Fellows.

At the recent poll of the Fellows upon this subject, out of 418 valid answers 268 voted in favour of election by the Fellows of the College, either with or without nomination by the Council, and 150 for the present method, thus showing a majority approaching to two-thirds in favour of a change being made in the mode of election of President. In view of such voting it appears to be due to the Fellows that the Council should take this question into careful consideration.

3. That no alteration in the constitution or external relations of the College shall be effected without the body corporate being convened to discuss such proposed alteration.[1]

This proposition has always been regarded by the Association as a fundamental principle, and as an almost self-evident constitutional axiom. Although this principle has never been seriously contested it has only been partially acted upon by the Council. It is, however, so vital to the well-being of the College that the Association feels it to be essential that it should be incorporated in a new Charter.

4. That the system of substitute members of council be abolished.

The Association is of opinion that all the members of the Council should be upon an equal footing in regard to their term of service, and that the apparent advantage to the constituency of the additional elections occasioned by the adoption of the system is outweighed by the inconvenience and possible hardship to the individual members of the Council elected as substitute members. If the more frequent elections are considered by the Council as an advantage, such advantage would be gained better by shortening the term of office of councillors to six years. It has been objected that the system of substitute members is necessary for the satisfactory technical working of the elections, but if the Charter was amended so as to give each elected member of the Council an eight-year term of office instead of compelling three members of the Council to retire annually there would be no difficulty. One year there might be more and another fewer vacancies, as, indeed, is the case at present more or less, but all the members of the Council would be on that footing of equality which is the object of the suggestion.

5. That members of the Council shall not be eligible for re-election after serving for two full periods of eight years.

It is felt by the Association that a period of sixteen years' service on the Council is ample from the point of view of the interests of the College, despite the fact that this period has been exceeded at present only in a limited number of instances.

6. That the Council shall have power to increase the number of the members of the Court of Examiners from ten, as now limited, to any number not exceeding twenty.

It is to be noted that the insertion of such a provision in a new Charter would not render an increase of the number of examiners compulsory upon the Council, but would allow the Council to appoint additional examiners if the necessity for an increase should arise, as it may do at any time. At present the work of members of the Court of Examiners is at least as exacting as they can discharge with advantage to the College and the candidates, and it cannot be expected that overworked examiners should discharge their duties satisfactorily. It would seem, therefore, obviously for the interest of the College that the Council should have power to increase the number of examiners, and such an increase might be of service either with a view to a fairer division of labour than now exists to admit of the appointment of examiners in special branches or for a more comprehensive representation of schools.

7. That members of the Court of Examiners of the Royal College of Surgeons of England shall be elected annually and that no member of the Court shall hold office for more than five consecutive years, and that at the expiration of this term he shall not be again eligible until after a period of two years has elapsed.

Under the present Charters a member of the Court of Examiners holds office for five consecutive years and is immediately re-eligible on the expiration of that term. This regulation is at variance with the general rules observed at

[1] In the original document sent to the secretary of the College the words "without the consent of the body corporate convened to discuss such alterations" were used owing to the transcription by mistake of an earlier form of a resolution passed at one of the general meetings at the College.

Digitized by Google

other licensing corporations in the election of surgical as well as other examiners. It is also at variance with the regulations adopted by the Council itself in respect to the appointment of examiners at the College in other subjects. This discrepancy is the more noteworthy because examination of candidates in anatomy and physiology formed a part of the duties of members of the Court of Examiners for many years, so that this curious condition of things exists—viz., that the rules adopted by the Council for the Board of Examiners in anatomy and physiology separated by the Council from the Court do not conform to the regulations of the Charter in respect to that Court. This fact alone would justify the Association in asking the Council to consent to apply for a new Charter, even if it were not supported by the obvious necessity that the Council should have an equal control over the surgical as over other examiners of the College.

8. That the meetings of the Fellows, the change in the mode of election of the President, the limitation of the terms of office of members of the Council and members of the Court of Examiners, and the annual general meeting of Fellows and Members for the reception of the report of the Council shall be provided for in a new Charter, and that the conduct of the meetings at the College and other matters referred to shall be regulated by by-law.

The changes already made by the Council and those suggested by the Association are of so great and even vital importance that they should be enacted in due form and regulated either by Charter or by-law. Regulations of the Council are not of sufficiently stable a character to give due weight to fundamental constitutional enactments, neither should it be left to the good pleasure of a fluctuating body like the Council to withdraw the privileges deliberately conferred upon the Fellows and Members for the good of the institution, the profession, and the public.

THE HEALTH OF THE CITY OF BELFAST FOR 1894.

DR. WHITAKER, medical officer of health for the city of Belfast, has just submitted his annual report, in which there are several very interesting matters. The number of deaths registered in 1894 is less than in either of the two previous years, while the death-rate from zymotic diseases is lower than in 1893, nearly 50 per cent. being caused by measles; while the deaths from phthisis and diseases of the respiratory organs are less numerous than they have been for many years past. In speaking of the cases of infectious disease, Dr. Whitaker admits that the returns are of little value because he has no means of ascertaining the number of cases other than those treated by the dispensary medical officers or at the Union Hospital. The Notification of Infectious Diseases Act is not in force in Belfast, and hence Dr. Whitaker has not the information medical officers have in many other cities, and we are afraid the late trial in Dublin, where a medical man was cast in damages, will tend very much to delay the desire of the authorities, or indeed, of medical men, to see this Act working in Belfast. At present the dispensary districts are co-extensive with the registrar's districts, and the medical officer of each of them is registrar and medical officer of health for his own division. In his report Dr. Whitaker gives the boundaries of these districts; we hope in his next work he will improve on this by adding a map of the city with the various registrars' districts clearly indicated. It would be a valuable addition to his report. Dr. Whitaker assumes the population for the past year to have been 285,000, and on this basis he calculates the birth-rate as 32·8 and the death-rate as 23·2. There were during the year 9349 births and 6615 deaths. Of these deaths, in 1894 2511, or more than one-third, were due to phthisis and respiratory diseases. The deaths from phthisis would seem in Belfast to be little influenced by either the seasons of the year or the state of the weather. The deaths from diarrhœa were less numerous than in any of the four preceding years. The number of deaths from typhoid fever shows an increase on the preceding year, and some facts stated by Dr. Whitaker are of great interest as bearing on the *quæstio vexata* of the etiology of this complaint. He finds that the greatest number of cases occurred in the neighbourhood of the Crumlin and Shankhill-roads—that is, in a district of Belfast which it would be expected would be one of the healthiest occupied by the working classes. It is well elevated above sea-level, its roads and streets, as Dr. Whitaker points out, are wide and open, its houses comparatively newly built, and yet enteric fever is more prevalent here than in other parts of Belfast inferior to it both in position and in sanitation. But there are other more puzzling features to be explained. In this district are placed the military barracks and the city prison, built on somewhat similar soil and supplied with water from the same source, and yet typhoid fever is practically unknown in these institutions. In the union workhouse (with between 3000 and 4000 inmates) only one case of typhoid fever was returned as sent into the hospital from this disease during the year, and the disease was not contracted in that house. In the deaf and dumb institution, adjoining, the same state of affairs has occurred—viz., no cases of typhoid fever—while in the lunatic asylum (a place very much overcrowded) no case of typhoid fever, or, indeed, of any contagious or infectious disease, has occurred during the past three years. From these facts Dr. Whitaker concludes that there is nothing naturally present in the air, soil or water, which would make typhoid fever more prevalent at Belfast than elsewhere, and that, if the same sanitary arrangements and regularity of living were adopted by the public generally that is carried out in the public institutions, this disease would be almost unknown in Belfast. Another explanation for the prevalence of typhoid fever in the Crumlin and Shankhill districts was given at the meeting of the Belfast board of guardians, on July 2nd, by Dr. Gibson. He stated that no fewer than forty-seven cows were without any supply of pure drinking water and were compelled to consume sewage or water contaminated with sewage on grazing land inside the city. The district referred to by Dr. Gibson is near to the Crumlin and Shankhill parts of the city, and the natural inference is that in this way, by the milk of cows drinking sewage, the disease may be transmitted. He thought the public health committee should have seen that a proper water-supply was obtained for the cows in the fields. In the district from which he (Dr. Gibson) came, Ballymacarrett, typhoid fever was entirely absent. In referring to diphtheria, Dr. Whitaker says the disease seems to be increasing in Belfast, an experience similar to that in England. Typhoid fever is dying out, and there were only 4 cases of small-pox—a very interesting fact considering the close connexion of Belfast and Dublin, where there has been such a great epidemic. Dr. Whitaker attributes the comparative freedom from small-pox to the prompt action taken to isolate and disinfect any house in which the disease occurs, but more particularly to the care taken, not only by the medical profession but also by the people themselves, in the matter of vaccination. Here are a few facts on the vaccination question given in this thoughtful report. In the year 1891 there were 25 cases of small-pox; of these, 23 patients had been vaccinated of whom one died; 2 were not vaccinated, and both, though young and strong, died. In 1893 there were 19 cases of small-pox, all of which were treated in the Union Hospital, and, although some of the cases were severe, there were no deaths, and in every case the patient had been vaccinated. In reference to the water-supply of Belfast, Dr. Frankland of Dundee, to whom Dr. Whitaker sent a supply for analysis, reports that "as regards the fitness of the water for the supply of a large city, it is of a medium quality for such a purpose." Other matters referred to by Dr. Whitaker in his most interesting report are the high infant mortality, the want of a suitable hospital for phthisis, the question of disinfection—especially in cases of small-pox and typhoid fever, the sanitary defects in schools and in working-class houses, and personal and home cleanliness.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF FELLOWS.

A MEETING of Fellows of the College was held on the 4th inst. at 5 P.M., the President, Mr. Christopher Heath, being in the chair. Forty-five Fellows, including fourteen members of the Council, were present. The Secretary having read the minutes of the meeting in January, the President said that since the last meeting the College had had to deplore the

Digitized by Google

loss by death of several distinguished Fellows; firstly, Mr. Hulke, who died while President and only a few days after the Hunterian Oration; he had perished through his devotion to duty, for his fatal illness had resulted from his going in the middle of the night during the severe winter weather to operate on a hospital patient; Sir William Savory also, who had held the position of President of the College for four years; Mr. Arthur Durham, who was for many years an active member of the Council; and, lastly, Mr. Thomas Huxley, who was elected a Fellow in 1883, who had the great honour of being a Privy Councillor, and whose wide knowledge had done so much to advance science.

The President then reported that the alterations in Sections 4, 16, and 25 of the By-laws had been approved by the late Home Secretary and the late Lord Chancellor, and had become by-laws of the College. The alterations in Section 4 provided that voting papers for the election of members of the Council be sent to all Fellows and permitted them to be received up to the time of the commencement of the election, and under this modified by-law the election on the 4th inst. was held. The alteration in Section 16 was to give increased power to the Council in dealing with cases of unprofessional conduct on the part of Fellows or Members of the College. Some opposition had been offered to the suggested change by some Members, and the late Home Secretary had advised the insertion of the words "after due inquiry," and in this modified form the by-law had been ordained. The third alteration increased the fee for the dental licence from ten to twenty guineas.

The President further stated that the Council had decided that it was not expedient to accede to the resolution passed at the meeting in January, but that a committee of the Council had been appointed to receive deputations from the Fellows of the College upon the subject of the resolution—viz., the question of the mode of election of the President. One deputation had been received, the matter was discussed, and a further meeting was to be held shortly. This concluded all the business on the agenda.

QUARTERLY MEETING OF THE COLLEGE: ELECTION OF PRESIDENT.

A quarterly meeting of the College was held on Thursday, July 11th, Mr. Christopher Heath, President, in the chair.

The President reported the result of the meeting of Fellows held on the preceding Thursday for the election of Members of the Council.

Mr. Christopher Heath was re-elected President of the College, and Mr. Reginald Harrison and Mr. Pickering Pick were appointed Vice-Presidents.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6420 births and 3564 deaths were registered during the week ending July 6th. The annual rate of mortality in these towns, which had risen in the three preceding weeks from 15·4 to 16·7 per 1000, further increased last week to 17·5. In London the rate was equal to 18·0 per 1000, while it averaged 17·2 in the thirty-two provincial towns. The lowest rates in these towns were 9·1 in Croydon, 10·0 in Brighton, 10·6 in Nottingham, 11·0 in Bristol, and 12·2 in Portsmouth; the highest rates were 20·1 in Newcastle-upon-Tyne, 20·4 in Blackburn, 21·4 in Bradford, 21·8 in Salford, and 24·4 in Liverpool. The 3564 deaths included 665 which were referred to the principal zymotic diseases, against 400 and 493 in the two preceding weeks; of these, 337 resulted from diarrhœa, 131 from measles, 71 from diphtheria, 62 from whooping-cough, 31 from scarlet fever, 25 from "fever" (principally enteric), and 8 from small-pox. No fatal case of any of these diseases occurred last week in Brighton, Huddersfield, or Halifax; in the other towns they caused the lowest death-rates in Gateshead, Portsmouth, and Croydon; and the highest rates in Liverpool, Leeds, Wolverhampton, West Ham, and Leicester. The greatest mortality from measles occurred in Newcastle-upon-Tyne, Plymouth, Manchester, Blackburn, and West Ham; from whooping-cough in Norwich, Derby, Burnley, Sunderland, and Bolton; and from diarrhœa in London, Cardiff, Salford, Wolverhampton, and Leicester. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 71 deaths from diphtheria included 53 in London, 4 in West Ham, 3 in Salford, and 3 in Leeds. Four fatal cases of small-pox were registered in Oldham, 3 in London, and 1 in Liverpool, but not one in any other of the thirty-three towns. There were 42 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, July 6th, against 19, 22, and 34 at the end of the three preceding weeks; 17 new cases were admitted during the week, against 2, 8, and 25 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2044, against 1637, 1732, and 1894 on the three preceding Saturdays; 311 new cases were admitted during the week, against 199, 251, and 319 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 186 and 160 in the two preceding weeks, were again 160 last week, and were 38 below the corrected average. The causes of 58, or 1·6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Nottingham, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·4 and 19·2 per 1000 in the two preceding weeks, rose again to 19·4 during the week ending July 6th, and exceeded by 1·9 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·7 in Perth and 14·9 in Leith to 21·4 in Glasgow and 25·1 in Greenock. The 560 deaths in these towns included 57 which were referred to diarrhœa, 18 to measles, 10 to whooping-cough, 5 to scarlet fever, 4 to diphtheria, 3 to "fever," and 1 to small-pox. In all, 98 deaths resulted from these principal zymotic diseases, against 76 and 78 in the two preceding weeks. These 98 deaths were equal to an annual rate of 3·4 per 1000, which slightly exceeded the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had increased from 25 to 48 in the three preceding weeks, further rose to 57 last week, of which 43 occurred in Glasgow, 3 in Edinburgh, and 3 in Paisley. The deaths referred to measles, which had been 14 in each of the three preceding weeks, rose to 18 last week, and included 7 in Glasgow and 5 in Paisley. The 10 fatal cases of whooping-cough exceeded by 1 the number in the preceding week, and included 5 in Glasgow and 3 in Aberdeen. The deaths from scarlet fever, which had been 7 and 1 in the two preceding weeks, were 5 last week, of which 4 occurred in Glasgow. The 4 fatal cases of diphtheria were within 1 of the number recorded in the preceding week, and included 2 in Glasgow, where the death from small-pox was also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 94 and 99 in the two preceding weeks, declined again to 79 last week, but exceeded by 22 the number in the corresponding week of last year. The causes of 33, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 20·1 and 22·4 per 1000 in the two preceding weeks, further rose to 24·9 during the week ending July 6th. During the thirteen weeks of the last quarter the death-rate in the city averaged 27·3 per 1000, the rate during the same period being 16·7 in London and 18·8 in Edinburgh. The 150 deaths registered in Dublin during the week under notice showed an increase of 17 upon the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against 16 and 9 in the two preceding weeks; of these, 6 resulted from diarrhœa, 2 from scarlet fever, 1 from diphtheria, 1 from whooping-cough, 1 from "fever," and not one either from small-pox or measles. These 11 deaths were equal to an annual rate of 1·6 per 1000, the zymotic death-rate during the same period being 4·0 in London

* Including 43 cases of membranous croup.

† Including deaths from membranous croup.

Digitized by Google

and 1·3 in Edinburgh. The fatal cases of diarrhœa, which had 3 and 5 in the two preceding weeks, further rose to 6 last week. The mortality from "fever" corresponded with that recorded in the preceding week, while that from whooping-cough showed a decline. The 167 deaths in Dublin last week included 35 of infants under one year of age, and 39 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded those recorded in any recent week. Seven inquest cases and 3 deaths from violence was registered; and 54, or nearly a third, of the deaths occurred in public institutions. The causes of 9, or more than 5 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JUNE, 1895.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during June in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 8·4 per 1000 of the population, estimated at 4,392,346 persons in the middle of the current year. In the three preceding months the rates had been 5·8, 5·7, and 6·8 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Kensington, Hammersmith, St. Martin-in-the-Fields, Strand, St. Olave Southwark, Lewisham, and Lee; while they showed the largest excess in Bethnal Green, Mile End Old Town, Poplar, Rotherhithe, Battersea, Woolwich, and Plumstead. The prevalence of small-pox in London showed an increase during June, 43 cases being notified during the month, including 12 in Camberwell, 4 in Lambeth. 3 in Westminster, and 3 in Bermondsey sanitary areas. The Metropolitan Asylum Hospitals contained 33 small-pox patients at the end of June, against 54, 34, and 20 at the end of the three preceding months; the weekly admissions averaged 10, against 11, 7, and 5 in the three preceding months. The prevalence of scarlet fever in London showed a further marked increase upon that recorded in recent months; this disease was proportionally most prevalent in Clerkenwell, St. George-in-the-East, Limehouse, Rotherhithe, Battersea, Greenwich, Woolwich, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 1845 scarlet fever patients at the end of June, against 1485, 1413, and 1481 at the end of the three preceding months; the weekly admissions averaged 229, against 145, 132, and 167 in the three preceding months. The prevalence of diphtheria in London showed a further increase during June; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, St. Luke, Whitechapel, Mile End Old Town, Poplar, Newington, and Rotherhithe. There were 633 cases of diphtheria under treatment in the Metropolitan Asylum hospitals at the end of June, against 435, 430, and 508 at the end of the three preceding months; the weekly admissions averaged 109, against 62, 69, and 81 in the three preceding months. The prevalence of enteric fever in London showed a marked decline during June; this disease was proportionally most prevalent in Marylebone, Woolwich, and Plumstead sanitary areas. Erysipelas was proportionally most prevalent in Marylebone, Holborn, Bethnal-green, Limehouse, and Rotherhithe sanitary areas. The 10 cases of puerperal fever notified during June were considerably below the average.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patient had previously resided. During the four weeks ending Saturday, June 29th, the deaths of 5019 persons belonging to London were registered, equal to an annual rate of 14·9 per 1000 of the population, against 30·0, 18·3, and 15·9 in the three preceding months. The lowest death-rates during June in the various sanitary areas were 8·4 in St. James Westminster, 9·4 in Wandsworth, 9·6 in Hampstead, 9·8 in Lewisham (excluding Penge), 10·0 in Stoke Newington, 11·1 in Lee, and 11·2 in Plumstead; the highest rates were 21·9 in St. George Southwark, 22·1 in Clerkenwell, 22·2 in Whitechapel and in Limehouse, 22·5 in Strand, 28·2 in St. George-in-the-East, and 30·7 in St. Luke. During the four weeks of June 765 deaths were referred to the principal zymotic diseases in London; of these, 262 resulted from measles, 178 from diarrhœa, 151 from diphtheria, 88 from whooping-cough, 58 from scarlet fever, 26 from different forms of "fever" (including 1 from typhus, 24 from enteric fever, and 1 from an ill-defined form of continued fever), and 2 from small-pox. These 765 deaths were equal to an annual rate of 2·3 per 1000, against 1·5 and 1·7 in the two preceding months. No fatal case of any of these diseases was registered during June in St. James Westminster, St. Olave Southwark, or Lee; in the other sanitary areas the lowest zymotic death-rates were recorded in Paddington, St. George Hanover Square, Hampstead, Strand, Wandsworth, and Lewisham; and the highest rates in St. Luke, Shoreditch, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, and Poplar. Only 2 fatal cases of small-pox were registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being 14; of these 2 fatal cases, 1 belonged to Hammersmith and 1 to St. Giles sanitary areas. The 262 deaths referred to measles were 23 below the corrected average; among the various sanitary areas this disease showed the highest proportional fatality in St. Luke, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, and Poplar. The 58 fatal cases of scarlet fever were 10 below the corrected average number; this disease showed the highest proportional fatality in Hackney, Clerkenwell, St. George-in-the-East, and Battersea sanitary areas. The 151 deaths referred to diphtheria exceeded by 37 the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, Bethnal Green, St. George-in-the-East, Mile End Old Town, Poplar, Bermondsey, and Rotherhithe. The 88 fatal cases of whooping-cough were less than half the corrected average number; this disease showed the highest proportional fatality in St. Giles, St. Luke, St. George Southwark, and Newington sanitary areas. The 24 deaths referred to enteric fever were 15 below the corrected average number; except in Plumstead, there was no marked excess of "fever" mortality in any of the sanitary areas during the month under notice. The 173 fatal cases of diarrhœa were 9 above the corrected average number. In conclusion, it may be stated that the mortality in London during June from these principal zymotic diseases was rather more than 12 per cent. below the average.

Infant mortality in London during June, measured by the proportion of deaths under one year of age to registered births, was equal to 123 per 1000, and was slightly below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Marylebone, Stoke Newington, Rotherhithe, Wandsworth, Lewisham, and Lee; and the highest rates in St. Martin-in-the-Fields, Clerkenwell, St. Luke, Shoreditch, Limehouse, and St. George Southwark.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR-GENERAL INKSON has proceeded to England on leave of absence, and the duties of Principal Medical Officer in Malta have been taken over by Brigade-Surgeon-Lieutenant-Colonel Lyons. Surgeon-Lieutenant Vaughan-Williams has been posted to Cork. Surgeon-Captain Hore has been transferred to York. Surgeon-Lieutenant C. M. Fleury, A.M.S., is ordered to York for duty in the North-Eastern District; he will return to Netley when his services are no longer necessary in that district. Surgeon-Lieutenant W. M. O'Connor, M.M.S., is attached to the Medical Division, and Surgeon-Lieutenant H. E. Mortis to the Surgical Division of the Royal Victoria Hospital.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major S. C. Sarkies is appointed to act as Surgeon, Third District, Madras, during the absence of Brigade-Surgeon-Lieutenant-Colonel H. J. Hazlett, on leave. Surgeon-Captain W. Molesworth is appointed to act as Additional Medical Officer, General Hospital, Madras, during the employment of Surgeon-Captain R. Robertson on other duty. Surgeon-Major J. Smyth is appointed to act as Fort Surgeon with Port and Marine duties, during the absence of Surgeon-Lieutenant-Colonel H. Allison on leave. Surgeon-Captain G. G. Giffard is appointed to act as Resident Medical Officer, General Hospital, during the employment of Surgeon-Major J. Smyth on other duty. The following appointments

Digitized by Google

and transfers are ordered, consequent on the departure on leave of Surgeon-Lieutenant-Colonel O. Baker:—Surgeon-Captain T. W. Gibbard to hold Collateral Charge of the Civil Surgeoncy at Shwebo; Surgeon-Captain K. Prasad to be Civil Surgeon of the Toungoo District; Surgeon-Captain A. R. P. Russell to be Superintendent of the Rangoon Central Gaol; and Surgeon-Major R. E. S. Davis to be Junior Civil Surgeon and Superintendent of the Lunatic Asylum, Rangoon. The services of Surgeon-Major E. F. H. Dobson (Bengal) are replaced at the disposal of the Chief Commissioner of Assam, from date on which he was relieved of his duties as Officiating Protector of Emigrants and Superintendent of Emigration, Calcutta.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Fleet-Surgeon Horace E. F. Cross to the *President* (additional) for temporary service at the Royal Naval rendezvous. Surgeons: C. S. Facey to the *Widgeon;* Bernard Ley to the *Resolution;* S. H. M'Sherry to the *Wallaroo*, and E. Cuffey to the Haulbowline Hospital.

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Buffs (East Kent Regiment): Surgeon-Major C. G. M. Lewis to be Surgeon-Lieutenant-Colonel; to resign his commission; to be granted permission to retain his rank, and to continue to wear the uniform of the Battalion on his retirement. 5th (Irish) Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant J. T. Walsh resigns his commission. 6th Volunteer Battalion the King's (Liverpool Regiment): Michael Joseph Mahony, M.B., to be Surgeon-Lieutenant. 1st (Exeter and South Devon) Volunteer Battalion the Devonshire Regiment: Surgeon-Lieutenant E. L. Puddicombe resigns his commission. 1st Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Surgeon-Major T. M. Dolan, M.D., to be Surgeon-Lieutenant-Colonel. 2nd Volunteer Battalion the Gordon Highlanders: Surgeon-Captain W. S. Cheyne, M.B., to be Surgeon-Major.

VENEREAL DISEASES IN THE ARMY OF INDIA.

The *Times of India* of the 14th ult. contains a correspondence in connexion with a quotation from THE LANCET on this subject in which this journal is alluded to as a "materialistic" organ. Well, it certainly strikes us as very material to the health and efficiency of our troops in India that unfortunate women when suffering from a highly contagious disease should not be allowed to follow their calling whilst in that condition, and we are glad to notice that the *Times of India*, in some very sensible and sarcastic remarks on the subject, takes the same view. Whether the amount of disease from this cause has been unduly raised or not by the inclusion of re-admissions among the admissions is a statistical matter that can be easily set right, but it does not seem to us to materially affect the question at issue. We repeat that it appears a monstrous absurdity to safeguard the troops against such diseases as cholera, small-pox, and infectious fevers by insisting on the prompt removal of the sufferers from them from cantonments and camps while we allow unfortunate women affected with venereal disease to carry on a calling that is highly dangerous to other people. It is surely a matter of common sense and common prudence to insist that a woman known to be suffering from this class of disease should either go to a hospital where she can be treated and cured or quit the cantonment. As it is at present, several soldiers may independently attribute the source of their infection to a common cause which we are powerless to treat or remove. This may be a very materialistic view to take of the subject, but it nevertheless seems to our medical apprehensions a very natural, common-sense way of looking at it. Whether, judged by past experience, the Lock Hospital system in India failed to accomplish all that was expected of it or not has little or no bearing on this point.

MEDICAL AND SANITARY ARRANGEMENTS IN MOUNTAIN WARFARE IN INDIA.

In a lecture recently delivered at the Royal United Service Institution by Major F. C. Carter, Royal Berkshire Regiment, on Mountain Warfare in India, special reference was made to the medical and sanitary arrangements for such expeditions. The lecturer said that however complete may be the organisation, equipment, and *morale* of our troops, they will avail little if the medical and sanitary arrangements are faulty. A great tendency to be avoided is the "cutting down" of the medical staff and the number of field hospitals required for hill campaigns, a tendency that has no doubt arisen partly from motives of economy and partly from the healthy state the troops have generally been in during our late frontier wars. The danger of such false economy was, however, clearly shown with the Isazai Field Force of 1892, when, owing to fever, sunstroke, and cholera following on an attempt to reduce the hospital establishment, the resources of the medical department with the force were severely taxed. Another medical question of some importance is the carrying of wounded men. The stretchers now in use are by no means suitable for steep hillsides. In mountain warfare, owing to the nature of the hills, the density of the jungle, or the ever-vigilant attitude of our foes, it is necessary for our camps and bivouacs to be confined within far closer limits than when fighting in the plains, and this alone necessitates a far more careful inspection of *minutiæ sanitatis* than is otherwise necessary. The necessity of ordinary precautions does not appeal to a native.

THE HEALTH OF THE FRENCH TROOPS IN MADAGASCAR.

It is not easy to form a correct estimate of the sanitary condition of the French force in Madagascar from the various reports that have been published on the subject. It seems, however, according to those received by the Minister for War in Paris, and published in the *Standard* of the 6th inst., that about one-fifteenth of the troops are in hospital, and about one-thirtieth, including the coolies employed with the French expeditionary force, are on the sick list, but not in hospital. The diurnal variations of temperature in Madagascar have to be taken into account—the nights are said to be very cool. From our experience in India and Afghanistan we know that much sickness is to be expected under such circumstances among the coolies and native followers with a force, and we are not therefore surprised to learn that a demand has been made on the French War Minister to send out woollen jerseys for their use. As might have been expected, the resistance offered to the French forces is comparatively small and easily overcome. A sanatorium has been erected at Nossi Bé, which when completed will accommodate 500 patients. It is occupied at present by about 200 sick soldiers from Majunga and elsewhere.

MILITIA MEDICAL STAFF CORPS.

The Hants Companies of the Militia Medical Staff Corps are encamped at Netley between the Royal Victoria Hospital and the lunatic asylum. The non-commissioned officers and men commenced their duties at the Royal Victoria Hospital on Monday, the 8th inst. They are employed as camp guards, cooks, messengers, and on fatigues, dispensary, pack-store, bathroom and ward duties. The companies parade daily in the morning with the Medical Staff Corps. The drills take place after 3 P.M. One non-commissioned officer and six men are furnished daily for night duty in the hospital.

THE VOLUNTEER MEDICAL STAFF.

His Royal Highness the Duke of Cambridge has accepted the invitation of the officers of Volunteer Medical Staff to dine with them at the King's Hall, Holborn Restaurant, on Wednesday, July 31st, at 7 P.M. Major-Generals Sir Francis Grenfell, G.C.M.G., K.C.B., Inspector-General for Auxiliary Forces, and Lord Methuen, C.B., C.M.G., Commanding the Home District, will be present on the occasion, when the chair will be taken by Surgeon-Lieutenant-Colonel W. R. Smith, M.D., F.R.S. Edin., 3rd V.B. the Queen's Own Royal West Kent Regiment.

WAR OFFICE POLICY OF THE NEW GOVERNMENT.

The army is waiting for a declaration of policy on the part of the new Government. As at present arranged, the Duke of Cambridge will resign his post in October, and all branches of the service are anxious to know who is to be his successor in the newly constructed appointment. Lord Wolseley, Lord Roberts, Sir Redvers Buller, and the Duke of Connaught have all been named, but nothing is definitely known as yet. It would probably not suit the Duke of Connaught to take the appointment (for five years) at the present time.

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on the 9th inst, Inspector-General T. Russel Pickthorn in the chair, the sum of £74 was distributed among the several applicants.

On Thursday afternoon last Captain Younghusband, in reading a paper upon the Chitral Campaign at the Royal

Digitized by Google

United Service Institution, drew special attention to the gallant conduct of Surgeon-Captain Whitchurch in bringing in Captain Baird when mortally wounded. We hope to learn shortly that this "gallant civilian," to adopt the Commander-in-Chief's pleasantry—has received the honourable distinction of the Victoria Cross.

Surgeon-General William Campbell Maclean, M.D., C.B., Madras Retired List, has been appointed Honorary Surgeon to the Queen in the room of Inspector-General of Hospitals J. H. Orr, M.D., C.B., deceased.

Correspondence.

"Audi alteram partem."

"IS METEOROLOGY A SCIENCE?"

To the Editors of THE LANCET.

SIRS,—Will Dr. Wilks please tell us what a "science" is? Some years ago there was a discussion whether medicine and surgery are sciences. I have for long been groping for a criterion, but in vain. It seems to be mainly a question of words, yet beneath the "counters" are conceptions of no small importance. Unless we recognise as a science a defined region of knowledge to which observation and inference are specially applied I see no foothold. But this would make meteorology as much a science as astronomy, and chemistry a more definite science even than astronomy. It would be easy to narrow the definition until it included only mathematics and psychology? It seems to me a mistake to mix up with the question that of "art." Every science has its application, and the extent of this has no relation to the features that determine the recognition of a "science." Surely, however, we may go too far. As we descend from the heights of "pure science," to which most of us look up with awe, we come to lower strata, with less distinction, to which, however, the adjective "scientific" is applicable, even with usefulness. And so we pass down to mere "knowledge." I write this in the hope of help from Dr. Wilks' clear thought.

I remain, Sirs, yours faithfully,

Queen Anne-street, Cavendish-square, W. W. R. GOWERS.

FRACTURE OF THE LOWER END OF THE FEMUR.

To the Editors of THE LANCET.

SIRS—In your report of the last clinical meeting of the West London Medico-Chirurgical Society you give prominence to the speakers who advocated treating the T-fractures (especially of the humerus) by the immediate application of plaster of Paris splints; in your abstract of the discussion that followed my cases you mention that Mr. Bidwell also recommended "that T-shaped fractures of the lower end of the humerus should be treated by a well-fitting plaster of Paris splint, which ought to be kept on for a month, and if the fracture had been kept completely immobilised the movements of the elbow-joint quickly returned without much trouble"—*vide* THE LANCET, June 29th. This is so contrary, I think, to what is unfortunately most usually the result of this description of accident, and also to the teaching of classic literature on the subject, that I would be glad to obtain the opinion of some of your surgical readers with large experience in this matter. In Mr. Christopher Heath's useful Surgical Dictionary, at page 746, when referring to T-fractures of the elbow-joint, Mr. Howard Marsh writes: "They are apt, particularly those which directly involve the joint, to be followed by impairment of movement in the limb, a fact of which it is best that parents at the onset should be informed." And this appears to me a prudent and timely caution; but if Mr. Bidwell's experience is usual it is both unnecessary and inadvisable, for it might tend to give needless anxiety to parents or guardians, as well as, perhaps, to tend to less careful attention and watchfulness of the surgeon.

I am, Sirs, your obedient servant,

July 8th, 1895. FREDERICK H. ALDERSON, M.D.

"THE POSITION OF THE MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—Your leading article on the question of the position of Members of the College of Surgeons in respect of their College is singularly opportune. There can, I think, be little question that the policy pursued by the great corporations with reference to the great mass of the profession has not been well advised, and it is doubtful whether it would even have been allowed in any profession but our own. When I say the policy, I mean the policy of denying to the mass of the profession, corporate existence, and I condemn this policy because the success of any body of citizens must depend upon the individuals composing that body; it must depend upon their efforts and not upon the action of the comparatively few who have arrived at coveted positions. The important question before the profession really is, What is the best method of quickening interest in affairs connected with the profession? At the present time the attitude assumed with regard to those who take an interest in professional politics is that they are the agitators, the riff-raff, the trades unionists of the profession. Now anyone who has in anyway studied the trades unions questions must arrive at the conclusion that the working men of this country, notwithstanding grave faults made in the working and management of those unions, have achieved a gigantic success, not only with reference to themselves, but also with reference to the community. One has only to compare labour conditions in Continental countries with those in our own to appreciate the fact that the working men of this country, by adhering to the principles of coöperation, friendly societies, and trades unions, have saved this country from a large amount of suffering and trouble. The best method, then, for advancing the interests of our profession must be one, I believe, which will induce each individual member to become alive to his professional responsibilities and to feel them. There is an association ready formed which has in it all the elements of success. I refer to the British Medical Association, which is representative and which is democratic in constitution. As yet this association has not become conscious of its latent power and force. In a few weeks it will be called upon to decide upon the following resolution, drawn up, after careful consideration, by a number of representative practitioners: "That it is to the interest of the public and of the medical profession that the Council of the British Medical Association should take power and authority to protect both the individual and the collective interests of the medical profession, and the Council be requested to take such steps as may be necessary to enable it to actively undertake these duties." I think that if members of the profession will come forward and help to carry this resolution they will be doing something much more practical than merely hammering at the old corporations. It appears to be much better policy to leave these close boroughs alone, and to convert the British Medical Association into a body powerful enough to cope with them. When the latter is done little fear need be felt as to the result. The association has the numbers besides possessing practically an unlimited field for raising funds. What would £1 per head alone mean for the campaign chest? The working men of this country subscribe very much more, in proportion to their means, to their own unions, and I do not believe for one instant that the members of our own profession would be unwilling to subscribe less in proportion to their earnings, supposing they felt that something substantial was being done for their interests.

I am, Sirs, your obedient servant,

Hatfield, July 7th, 1895. LOVELL DRAGE.

"THE REMUNERATION OF MEDICAL OFFICERS TO PROVIDENT ASSOCIATIONS, CLUBS, ETC."

To the Editors of THE LANCET.

SIRS,—Mr. W. G. Dickinson, in THE LANCET of July 6th, declines to accept the figures I used in my letter of June 22nd. I will accept his. In his illustration a club contributes £200 a year, subscribed by 1000 members, for the maintenance of a medical officer who may expect to have to pay 9000 visits in a year. That is 5·3*d.* per visit. Ignoring the home consultations, the value of the certificates, and the fact that the officer has to

Digitized by Google

find medicines out of this, as well as furnish, warm, and light a waiting-room and surgery, he has, moreover, to provide his own conveyance or walk. Is there a cabman in all London who would take a medical man on a round of twenty-five visits for half-a-guinea? Even accepting Mr. Dickinson's figures we find that a club officer's pay is less than that of a cabman! The amount of benevolent work done, over and above all this practically unpaid work of parish and club, is perhaps shown by the following calculation. Take the number of patients seen by the charities included in the Hospital Sunday Fund appeal at 1,500,000. At one shilling each this is worth £75,000. Take the profession as being in the proportion of 1 to 1000 of the total population, and it follows that before the public subscribe equally to the relief of the indigent sick they must contribute, not £40,000, but £75,000,000!—I am, Sirs, yours faithfully,

July, 1895. E. PAGET THURSTAN.

"THE MISUSE OF HOSPITALS."

To the Editors of THE LANCET.

SIRS,—The statistics published in the special supplement of the *Hospital*, showing that during 1894 no fewer than 1,300,650 separate out-patients were treated in the metropolitan hospitals, may well excite comment and surprise. There is good ground to doubt whether entirely satisfactory means exist at the different hospitals for separating the first visits from the second and subsequent visits of the same out-patients, in which case the number of these out-patients is probably to some extent over-stated in the *Hospital* statistics. The independent figures which were published in THE LANCET Hospital Sunday Fund Supplement, however, to a considerable extent corroborate them, and it will be useful to compare some of the figures in the two returns. THE LANCET figures purport to show the number of out-patients' visits. Thus, in twenty-four of the principal general hospitals 1,565,978 out-patients' visits were recorded during 1894, whereas the *Hospital* in the same twenty-four hospitals reports 622,399 distinct patients under treatment. Assuming that both these returns are approximately correct, the figures show that each patient averaged 2·5 visits during the year. Without hazarding any opinion as to the probable degree of accuracy of these two sets of returns, their comparison shows, at any rate, that the *Hospital's* figures cannot be explained away by the suggestion of blunder made by your correspondent, Mr. D. Biddle, although he correctly points out that a considerable number of the institutions draw both in-patients and out-patients from a far larger area than that of London proper. The editor of the *Hospital* asserts that the only known source of error in his figures is "the possibility that in some cases the same patient may have attended at more than one hospital during the year." It is impossible to doubt that this source of error is more than a possibility, but, unfortunately, there are no means for gauging the extent of the error. It should, however, be borne in mind that of the 1,300,650 distinct out-patients recorded in his tables, 622,399 were stated to have been treated in the larger general hospitals, 429 894 in special and in smaller general hospitals, and 248,357 in dispensaries. Nothing is more certain than that many of the out-patients, who were treated at the dispensaries and at the dental, ophthalmic, and other special hospitals, also repaired during the year to the out-patient department of one or other of the general hospitals.

The figures to which I have referred are doubtlessly startling, and, after due allowance for a certain amount of exaggeration from causes referred to above, afford abundant evidence of the misuse of hospitals. We must all entirely agree with Mr. Biddle in denouncing the recent enormous extension of hospital accommodation, more especially in the out-patient department, which not only tends to pauperise a rapidly increasing proportion of the community, but severely over-taxes the resources of institutions many of which are on the brink of bankruptcy.

I am, Sirs, yours faithfully,

July 10th, 1895. F.S.S.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Fellows on July 4th Mr. John Lentaigne, F.R.C.S., surgeon to the Mater Misericordiæ Hospital, was unanimously elected a member of the Council of the College in the room of Sir George Porter, Bart., deceased.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday Fund.

THE twenty-first annual collection just concluded has realised the handsome sum of £12 500, including a donation of £223 15*s.* 4*d.* from Mr. J. C. Holder. In the disposition of this large amount it was stated at the meeting that £10 000 was distributed among the medical charities of the city, £2000 was transferred to the credit of the convalescent homes, £137 10*s.* was appropriated under the terms of the agreemant with the District Nursing Society, and £150 was placed at the disposal of the applications subcommittee, among other objects, to enable them to provide surgical appliances and instruments and artificial limbs. The expenditure amounted to 4 0 per cent. of the amount received. The report of the Tyn y Coed stated that during the year 645 patients had been admitted; the average length of stay was 17·53 days; the cost per patient, including wages and all expenses of administration, was 15*s* per visitor per week. The sum expended in railway fares was over £100 a year. Altogether the outlook was very promising, and the success of the movement in its various directions undoubted.

Poisoning by Phenacetin.

A manufacturing chemist, aged fifty-four, was subject to attacks of headache. Recently he called at a shop for a dose of phenacetin, as this drug had often given him relief. On taking the dose given to him by the chemist he noticed that it had a bitter taste. He became stiff, convulsed, and in pain; a medical man was sent for who advised his removal to the hospital, and on his way there he died. The preliminary inquiry was adjourned in order that an examination might be made of the contents of the bottle from which the powder was taken. Any expression of opinion at the present time would be unjustified.

Steam Trams.

Periodically the residents on the lines of the steam trams write to the papers complaining of the vile effluvia and the dreadful noise caused by the engines. The hot weather intensifies these evils; but, apart from this, the grievance is a real one, and sadly interferes with the comfort of those whose lives are spent along the route of these unwieldy, odious monsters.

The New Small-pox Hospital.

The first patient was admitted to the new building on the first day of the present month. Up to that day there had been no case of small-pox in the city for ten weeks. In this instance the case was a mild one, but the officers of the Health Committee have not been able to trace the source from which it started. The health of the city continues to be good. The death-rates for the weeks ending June 22nd and 29th were only 16 9 and 16·1 respectively, and the zymotic rates were 1·6 and 1·9. During the latter week there were no deaths from measles or from typhoid fever. There were but two each from scarlet fever and diphtheria, but there were ten from diarrhœa, no doubt due to the effect of the hot weather upon children.

The Kyrle Society.

Health and happiness is the object of this society. The annual meeting of June 28th showed how largely the various influences of the society contributed to promote the interest and occupations of the young. An energetic executive and a willing staff work ungrudgingly to realise the object of those who devote time and money to the cause.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday and Sunday Fund.

A MEETING of delegates from firms subscribing annually to this Fund in Manchester and Salford and surrounding towns was held on Tuesday last in the Lord Mayor's Parlour. It was called to consider a proposal for the formation of a Workman's Auxiliary Society to coöperate with the general committee of the Fund in the arrangements for collections for the various hospital and charities in Manchester and Salford. The Mayor of Salford presided in the absence of

Digitized by Google

the Lord Mayor. Mr. F. Scott, the secretary, explained the scheme in detail, saying that the committee had long felt that the amount coming from the working classes had very inadequately represented their powers of contributing to these charities, which were so great a boon to them. Certainly these towns do not stand well when compared with Birmingham, which collected this year no less than £13,000, or with Glasgow and Leeds, the former of which contributed rather more and the latter rather less than £6000, while Manchester and Salford, with a population of 750,000, only raised £4000. The proposed society will provide a much more efficient organisation than has hitherto existed, and will be composed as follows: In the case of firms contributing to the Hospital Sunday collections, the workpeople should appoint a delegate, and these delegates should form the Society. The Society should then appoint a general committee, which should select, say, a dozen representatives to serve on the committee of the hospital fund, and help that committee to distribute the funds. The general committee of the Workman's Society would be further divided into smaller excutive committees, whose duty it should be to look after the collectors, who should, as far as possible, consist of the delegates sent by the workpeople. The delegates would undertake the duty of collecting the contributions of the workpeople in the respective works. It seems that last year the total deficit of the various local charities was £14,500. If this cannot be reduced curtailment of "the beneficent work of the hospitals" must follow. In appealing to the working classes of Manchester and Salford Mr. Scott said he was only appealing to their self-reliance and independence. The suggested scheme was warmly approved, and a number of proposals from the delegates present were submitted to the meeting. One very practical suggestion was to change the date of the annual collection from February to Midsummer, as it was thought the poorer classes would then be able to contribute more freely than in winter when money was more needed.

Potato Pie at the Salford Workhouse.

The dietary at the above institution has from time to time been commented on more or less adversely in the local press and in your columns, and although the medical officer does not seem to have drawn attention to the negative virtues of the tea, he has something positive to say about the potato pie. The minutes of the house committee contain the following report by him: "July 2nd, 1895. The pastry of the potato pie given to the children is quite unfit for them, as it is doughy and indigestible. The children refuse to eat it in the sheds. The pastry is from three to four inches thick. Potato pie for children aged from three to five years is not proper food." Few will dispute the soundness of this opinion, except, perhaps, the Salford guardians. However, the committee very considerately recommended "that the pies be better cooked, and the crust made thinner, so that it can be properly baked." Lancashire mouths are sometimes said to have a character of their own, and it would be interesting to observe the effect of a course or two of pastry four inches thick on the human face divine in the early and plastic period. It is satisfactory to see that the salary of the medical officer, Dr. A. C. Clarke, is to be raised from £100 to £130 per annum, notwithstanding his report on the qualities of the potato pie.

Manchester Medical Staff Corps.

The annual inspection of the 4th (Manchester) Division Volunteer Medical Staff Corps took place on the 6th inst. It was established in 1887, its original members being ten medical students, but its progress has been remarkably rapid and the full complement has been exceeded for several years. Surgeon-Major W. H. B. Crockwell, V.D., was in command of the corps, and the other officers on duty were Surgeon-Captains W. Coates, I. J. Renshaw, J. J. Kent Fairclough and H. B. Mann, Captain B. R. Howell, Quartermaster Dickinson, and the Rev. Canon J. D. Kelly, chaplain. About 250 of all ranks paraded, exclusive of 36 band and buglers. Surgeon-Colonel Muir, principal medical officer of the north-western district, from the Chester depôt, was the inspecting officer, and the visitors included Surgeon-Lieutenant-Colonel Cayzer of the 6th Lancashire Artillery. The members of the corps were in heavy marching order, carrying the full Slade-Wallace equipment which is in use in the army, but of which they are the only possessors among the Lancashire volunteers. After marching past in very good style a considerable time was passed in the exercise of the companies under their own officers in drills specially connected with medical staff work. No. 2 company had stretcher drill, whilst No. 1 company formed a collecting station, sending out parties to deal with and bring in wounded men from the field. Forty men of the Royal Welsh Fusiliers played the part of the wounded. Colonel Muir, in addressing the members of the corps, said the turn-out was exceedingly creditable to them, and he thought he could tell from the way in which they had performed their duty that day that they all took an interest in their work. It showed that they had been well trained, and great credit was due to their officers and instructors.

Vagrancy.

The Chorlton board of guardians at their last meeting resolved to send a petition to the Local Government Board praying them to institute an inquiry into the present mode of dealing with the casual poor, and into the best way of dealing generally with the great increase of vagrancy. The board state that there is a very prevalent opinion among Poor-law guardians that such an inquiry would lead to some more satisfactory scheme for placing casual relief on a better basis, both as regards the relief administered, the classification of the recipients, and the reimbursement of the cost, and they pray the Board to institute such an inquiry without delay, and adopt such other measures in this behalf as may seem to them to be either expedient or necessary.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Medical Officer of Health of Edinburgh.

AT the last meeting of the public health committee of the town council of Edinburgh the convener congratulated Sir H. D. Littlejohn on the honour which the Crown had conferred upon him. Sir Henry Littlejohn, in thanking the committee, said the honour was due to his being medical officer of health for the city.

The Edinburgh Obstetrical Society and Midwives.

An afternoon meeting of the Edinburgh Obstetrical Society is to be held on Wednesday, July 10th, when there is to be a discussion on "The condition of midwives in Scotland, with special reference to the question of registration. Should midwives be registered in Scotland?" It is expected that the country Fellows will take a prominent part in the discussion. The raising of this question in Scotland has been the outcome of the interest manifested in it on the other side of the Border. The question in Scotland does not appear to be so acute as in England; in fact, little or nothing was heard of it until the question of registration was raised. After the discussion the Fellows are to dine together, and it has been proposed to make Professor Simpson the guest of the evening, as the twenty-fifth anniversary of his appointment to the chair of Midwifery in the University occurs near this date.

The Extra-mural School of Medicine in Edinburgh and the Royal Colleges.

For some time past a movement has been in the air, if not exactly on foot, to bring the Royal Colleges of Physicians and of Surgeons in Edinburgh into closer relations with the extra-mural school than has been the case in recent years. Proposals have been made to the Colleges, and these are now being discussed and decided on by them. It is understood that the University is hostile to any arrangement which would more closely identify the extra-mural school with the Royal Colleges than it is at present, presumably because they fear that anything which might add to the prestige or status of the school might be hurtful to the University. If the view of the University continues to be expressed as it has been, it will probably lead to some scheme being adopted which, without this opposition, would have little chance of being accepted by the Colleges.

The Proposed New City Hospital for Edinburgh.

As was mentioned in THE LANCET some time ago, alternate sites for a new city hospital have been suggested to the town council. One of these—namely, that at Craiglockhart—has been visited by the Lord Provost and some of the town council, and a suitable site provisionally approved of. The ground extends to nineteen acres, and is situated near the Craiglockhart Poorhouse. The matter will come up before the town council at its next meeting.

Complimentary Dinner to Professor Simpson, Edinburgh.

Last week Professor Simpson was entertained to dinner by a number of his old assistants, it being the semi-jubilee of his appointment to the chair of Midwifery in the University. Dr. Halliday Croom occupied the chair, and there were a number of guests present.

St. Andrews University and Dundee.

Principal Peterson, in his closing address to the students of University College, Dundee, referred at length to the litigation as a result of which the agreement between the College and the University of St. Andrews has been dissolved. He denied that those at whose instigation this had been brought about represented the genuine opinion of the University, and denounced their action as based upon a desire to maintain a monopoly of teaching. In his view union would be advantageous to both institutions, and he would have no hesitation in leaving the question for settlement in the hands of a commission duly appointed for the purpose. The Dundee authorities were quite ready to discuss any practicable scheme and to give effect to any reasonable demand that might be made upon them. The Principal acknowledged the encouragement and sympathy offered to Dundee in the present trying circumstances by the Universities of Edinburgh and Glasgow, both of which have agreed to recognise the medical curriculum at Dundee as qualifying for graduation. This will be the last appearance of Mr. Peterson as Principal of Dundee College, as he has accepted the Principalship of the M'Gill College, Montreal.

St. Mungo's College, Glasgow.

The closing address of the present session of the Medico-Chirurgical Society was delivered by Dr. D. C. McVail, who took for his subject the Life and Work of the Doctor. The lecturer discussed the contrasts afforded by a comparison of the work of the merchant or the manufacturer and that of the medical practitioner, pointing out the self-sacrifice demanded of the latter if he would attain a high ideal of professional duty. He warned the students against the danger of becoming mere students and practitioners of the art of pleasing, and impressed upon them the grave responsibilities, both to their patients and the public generally, which they would undertake when they entered on the practice of their profession. A cordial vote of thanks was awarded to Dr. McVail for his address.

St. Andrews Ambulance Association.

At the annual meeting of the association the executive committee reported that the number of pupils trained during the year had been 6066, and there had been 3150 calls upon the waggons of the association. The total income for the year was £963 0*s.* 5*d.* and the expenditure £994 11*s.* 2*d.* The report also stated that a third edition, completing the fifteenth thousand, of the "Ambulance Handbook" by Dr. George T. Beatson is almost exhausted, and that the sale of Dr. Brodie's manual on stretcher-drill and exercise had also been large. Since the foundation of the association in 1892 a total of 21,126 patients have been conveyed in the society's waggons.

The Sanitary Association of Scotland.

At a recent meeting of the Board of Examiners certificates of competency in sanitary science were granted to ten out of eighteen candidates. The examiners were Dr. J. C. McVail, Dr. Eben. Duncan, Mr. Peter Fyfe, and Mr. G. A. D. Mackay.

Presentation to Dr. George Halket, Glasgow.

The members of the Royal Thistle Lodge of the Order of Foresters have presented their medical officer, Dr. George Halket, with a bookcase and aneroid barometer as a token of their esteem and respect. The presentation also included a gold ring set with rubies for Mrs. Halket.

The General Election.

The name of Mr. Robertson Watson, the lecturer on chemistry in Anderson's College, is mentioned as a probable candidate, representing the Labour interest, for the Bridgeton Division of Glasgow. This is the division of the city represented in the last Parliament by Sir George Trevelyan. Professor Murdoch Cameron is, as at a former election, appearing on the platform as an energetic supporter of Sir Charles Cameron, the Gladstonian candidate for the Central Division. There is no rumour of opposition to Mr. James A. Campbell, LL.D., who has for many years represented the Universities of Glasgow and Aberdeen. Mr. Campbell is a brother of Sir Henry Campbell-Bannerman, but sits on the opposite side of the House.

Glasgow Royal Infirmary.

Dr. Charles Workman has been appointed pathologist in place of Dr. Lindsay Steven, who has been promoted to be physician to the infirmary. Dr. Workman has for some years acted as assistant to the pathologist. He is a graduate of the Queen's University, Ireland.—Dr. Luke has been appointed one of the surgeons to the out-patient department of the infirmary.

Anderson's College Medical School, Glasgow.

The summer session at this school closed on the 5th inst. It has proved the most successful summer session in the history of the institution, upwards of 175 students having been in attendance, a number far in advance of any previous year. This, following on such a successful winter session as that of 1894-95, augurs well for the future of this school, which seems now to have entered upon a career of renewed usefulness and prosperity.

University of Aberdeen—the Quatercentenary Celebration.

The modified programme proposes that the celebrations should extend from Tuesday, Oct. 22nd next, to Friday, Oct. 25th, inclusive. On the Tuesday from 8 to 11 it is intended to have a grand reception of delegates. All the halls and laboratories of Marischal College will be open for inspection, and there will be a musical performance in the Mitchell Hall. This splendid hall will be inaugurated on Wednesday, the 23rd. The clock will be started at 11 A.M., and all the tower bells in the city will chime their best. The inauguration of the Students' Union will follow. The Students' representative council will present an address to Dr. Charles Mitchell, of Jesmond Towers, Newcastle, the donor of the union, who will afterwards entertain a number of them and other gentlemen at luncheon. On Thursday, at noon, Dr. Mitchell will be presented with the freedom of the city, and, in accordance with ancient custom, will be expected to deliver an address. A distinguished company will afterwards be entertained at luncheon by Lord Provost Stewart, who is himself a graduate (in arts) of the university. At 4 P.M. on the same day the Marquis of Huntly will deliver his rectorial address in the Graduation Hall, and a great torchlight procession of students will start at 8.30. On Friday a commemorative medal and address on behalf of the university authorities will be presented to Dr. Mitchell. At the same time the honorary degrees of D.D. and LL.D. will be conferred on a number of gentlemen. A service *in memoriam* of Bishop Elphinstone, founder of the university, will be held in King's College chapel, and the Duke of Richmond and Gordon (the Chancellor of the University), the Marquis of Huntly (Lord Rector), Dr. Mitchell, and others will be entertained at dinner by the University Court and Senatus. In view of these ceremonials the builders are pushing on the building operations at the north wing. The Mitchell Hall will be ready in good time. The Mitchell Tower (260 feet high) is finished. The only fatal accident in connexion with its erection occurred in the removal of the scaffolding, when a young man was killed by a fall of about 75 feet. *Alumni* abroad have not forgotten their *alma mater*. Further contributions (700 rupees in all) have just been sent from India through Dr. King, Botanic Gardens, Calcutta, including subscriptions from Surgeon-Captain Roberts, Bengal Medical Service; Surgeon-Colonel G. Thompson, Bengal Medical Service; Surgeon-Captain W. H. Gray, Bengal Medical Service; and Surgeon-Lieutenant-Colonel Hugh Johnston, Bengal Medical Service. The Liberal Government declined to give any further contributions from Imperial funds to the extension scheme. Should the Unionists succeed a further application will be made.

Forfarshire Medical Association.

The thirty-seventh annual general meeting of the Forfarshire Medical Association was held in the County Hotel, Forfar, on July 4th, Mr. Cable, President, being in the chair. The members present included Drs. J. W. Miller, Duncan, Stalker, Johnstone, Templeman, and Peter Campbell (Dundee), Drs. Alexander, McLagan-Wedderburn, Hunter, and M'Alister (Forfar), and Mr. Anderson Peters (Arbroath). Apologies for absence were intimated from Drs. A. M. Buchanan and Samson Gemmel (Glasgow), Surgeon Sharples, R.N., Dr. Urquhart (Perth), and from the President and Secretary of the Fifeshire Medical Association. The

Digitized by Google

minutes of the last meeting having been read and approved, the secretary then read the financial report, which showed the association to be in a satisfactory condition. The office-bearers for the ensuing year were elected as follows: President, Dr. Adam (Brechin); vice-presidents, Dr. Johnstone (Dundee) and Dr. Hunter (Forfar); council, Drs. J. W. Miller, Sinclair, Buist, Mackie Whyte, Mackay, and Mr. Steele Moon; secretary, Dr. Peter Campbell; treasurer, Dr. McGillivray; local secretaries, Dr. Key (Montrose) and Mr. Cable (Forfar), Dr. Laing (Arbroath) and Dr. Adam (Brechin). On the motion of Dr. Templeman, seconded by Dr. McLagan-Wedderburn, it was agreed that the usual donation of three guineas be handed over to the British Medical Benevolent Fund. The President afterwards delivered an address on Micro-organisms and Disease, for which he was awarded the cordial thanks of the meeting. It was arranged that the next meeting of the association should be held at Edzell.

July 9th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Medical Honours.

WE have had pleasure in hearing that his Excellency Lord Houghton, on retiring from the post of Lord-Lieutenant of Ireland, has conferred the honour of Knighthood upon Dr. Christopher Nixon and Mr. Thornley Stoker, of Dublin. Dr. Nixon was Physician-in-Ordinary to the Lord-Lieutenant. He is senior physician to the Mater Misericordiæ Hospital, Professor of the Practice of Medicine at the Roman Catholic University of Dublin, and visiting physician to the Central Asylum at Dundrum. Mr. Stoker is President of the Royal College of Surgeons in Ireland, and M.D. of the Royal University of Ireland. He is surgeon to the Richmond Hospital, and is a Government inspector for Ireland under the Vivisection Act. Sir Philip Smyly, M.D., F.R.C.S.I., has been appointed Surgeon-in-Ordinary to the Queen in Ireland, in the room of Sir George Porter, Bart., lately deceased. Sir Philip Smyly is the representative of the Royal College of Surgeons in Ireland on the General Medical Council. He is also surgeon to the Meath Hospital and held the post of Surgeon-in-Ordinary to the Lord-Lieutenant from 1869 to 1892.

Trinity College, Dublin.

The board of Trinity College, acting on the advice of a committee of the professors in the School of Physic, has elected Dr. A. C. O'Sullivan, M.A., M.B., Professor of Pathology to the school.

Supposed Case of Poisoning in Larne.

A good deal of uneasiness and excitement occurred recently in Larne owing to the sudden death of a woman aged seventy on June 11th. She fell ill shortly after eating veal, and notwithstanding everything Dr. Killen (who gave it as his opinion that the disease was caused by the veal) did she died. At the inquest, on the suggestion of the coroner, the viscera were sent to Mr. J. F. W. Hodges, F.I.C., Government analyst, and an adjournment made until last week, when Mr. Hodges reported that he could not find mineral or animal poison, but that he had succeeded in extracting an alkaloidal body having almost all the characteristic reactions of ptomaines. The verdict was that she died from inflammation of the bowels and stomach following on the ingestion of veal, the said veal being at the time unfit for food. The jury added that they considered that the man who sold the veal did not know that it was diseased.

Belfast Lunatic Asylum.

At a meeting of governors of the Belfast Asylum held on July 8th the committee appointed on June 10th to consider the whole question of accommodation to be provided for in the asylum district reported that at present there were on asylum books 425 patients, while it was proposed to transfer 150 from the workhouse; that meant 575 to be provided for. Now the existing City Asylum will accommodate 400, Purdysburn House 80, while the estimated increase for seven years was 155. The committee recommended that a detached self-contained building to accommodate 250 chronic patients should be erected at Purdysburn, the building to be so arranged as to be capable of being hereafter adapted for 150 acute cases, and that competitive plans and estimates for such a building should be invited, and that the competing architects (restricted to the profession in Belfast) should submit complete plans and estimates for a large asylum capable of containing 600 patients, and that a conference should be held between the professional members of the Board of Control, its consulting architect, and the governors, to determine the site for the proposed buildings, and to discuss the subject of the proposed competition. The report was adopted with the substitution of "sketch" plan for "complete" plan. The report of the committee advising the new asylum to be lighted by electricity was passed.

Peculiar Committal to the Belfast Lunatic Asylum.

Dr. Merrick, resident medical superintendent of the asylum, reported to the governors at their meeting on June 8th a very peculiar case. It appears that a militiaman who had been ill some four months ago was sent to the asylum last week on a committal order signed by the military authorities. However, when the man was examined by Dr. Merrick and his colleagues he was found to be not insane; but as their order was to place the man under surveillance for a month they had no option but to do so. Dr. Merrick thought that the detention of the man was a grave interference with the liberty of the subject, but as he said, in reply to several inquiries, that the board had no power to interfere, the matter dropped.

The Summer Session, Belfast.

The present summer session will come to a conclusion at the hospital this week, and at Queen's College next week.

Extensive Poisoning in a Young Ladies' Boarding School: Seventy Inmates attacked, with two Deaths.

Laurel Hill Convent in Limerick is an educational institution of considerable repute in which Roman Catholic young ladies are trained by a community of nuns. Considerable consternation existed there last Wednesday, when it was found that nearly all the inmates were suddenly attacked by diarrhœa and vomiting. The services of Dr. M. Malone, physician to the convent, were requisitioned, and as he found that he had to deal promptly with seventy patients, all more or less seriously ill, he prudently called in the assistance of Mr. Humphrys, Dr. Graham, Mr. Shanahan, and Dr. Haran, but, despite all their exertions, two of the nuns succumbed. One died shortly before 12 o'clock on Friday night, and the other died on Monday morning. An inquest was held on Saturday to inquire into the circumstances attending the death of the former. The evidence showed that the nuns and young ladies dined at 12 o'clock on Wednesday, the dinner consisting of soup, roast mutton, cabbage, new potatoes, custard, and strawberries. There was afternoon tea at 4 o'clock, and at that meal nothing but bread-and-butter and tea were served. The deceased was the first attacked, and she complained at half-past five o'clock. All the others were invalided soon afterwards. The only members of the whole household who escaped were the reverend mother, who was confined to her room owing to ill-health, and the sister who attended her. Attention was naturally riveted on what those two ladies had or had not partaken of, and it was ascertained that the reverend mother had not eaten either the soup or the custard. The attending sister had not taken any of the custard, but she thinks she had had some of the soup. Apparently, then, the irritant poison, whatever it may have been, was in either the custard or the soup. Possibly, of course, the water, which was the only drink at dinner, or one of the articles at afternoon tea may have contained it. The evidence of the cook, who is herself one of the victims, was taken. She states that the roast mutton was quite good; the custard consisted of eggs, milk, cornflour, and sugar; the soup was made from beef and mutton, flavoured with young celery with all the green leaves attached; the kitchen utensils she used contained neither copper nor brass. It also transpired that Sir Charles Cameron of Dublin found nothing deleterious in the sample of cornflour submitted to him for analysis. That being so, it is important to recollect the evidence given by the cook with regard to the celery, as botanical works state that unblanched celery is capable of producing poisonous results. The inquest was adjourned, and the coroner directed that a post-mortem examination should be held with a view to ascertaining whether an irritant poison such as arsenic could through any chance have been mixed with the food. The parents of the young ladies are naturally in a great state of anxiety, but I am glad to learn that nearly all the remaining sufferers are now convalescent.

July 9th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Presentation of Medals to Dr. Roux.

AT the end of last year the Municipal Council decided to offer, on behalf of the City of Paris, a medal to Dr. Roux, "pour rendre un solennel hommage à ses beaux travaux scientifiques si utiles à l'humanité." The Conseil Général of the department of the Seine adopted a similar resolution a few days later. Two gold medals were accordingly struck bearing on one side the effigy of the Republic designed by Chaplain, and on the other the words "A Docteur Émile Roux, le Département de la Seine," and "Au Docteur Roux, la Ville de Paris." The ceremony of presentation took place on Thursday last at the Hôtel de Ville, where there awaited our eminent confrère the members of the Bureaux of the two Councils, the Prefect of the Seine, and the Prefect of Police. In the course of the complimentary references made by the President of the Municipal Council to Dr. Roux's researches on diphtheria, he said: "Vous avez droit au plus précieux des remerciements, à celui des mères que vous avez rassurées et dont vous avez calmé les angoisses." The following letter from M. Pasteur was then read:—

"Monsieur le Président,

"Je regrette infiniment d'être dans l'impossibilité de me rendre à l'invitation que vous m'avez fait l'honneur de m'adresser. Lorsqu'en 1892 le président du Conseil municipal m'exprimait les vœux des élus de Paris et me parlait de la reconnaissance populaire, il me causait une de ces émotions qui font que toute une vie de travail se trouve récompensée en une minute et par un mot. Rien ne semblait pouver dépasser la joie que vous m'aviez donnée en ce jour de mes soixante-dix ans. Et cependant, ce que la municipalité de Paris veut faire aujourd'hui me touche encore davantage. Vous fêtez celui qui fut mon élève, mon cher collaborateur, M. Roux. Ce que j'aurais voulu dire devant lui et après vous, Monsieur le Président, c'est qu'en dehors des services rendus à la population parisienne par le traitement de diphtérie M. Roux contribue par ses cours à l'Institut Pasteur à répandre dans le monde entier une part d'influence française. Ainsi se continue, grâce à lui, aux chefs de service et aux préparateurs, l'œuvre que j'ai rêvée: laboratoires de recherches, laboratoires d'enseignement, travaux de longue patience pour arriver soit aux découvertes, soit au développement de certaines méthodes et leçons professées pour faire connaître une science nouvelle. Je remercie encore le Conseil municipal de ce qu'il a fait pour moi, de l'hommage qu'il offre aujourd'hui aux services rendus par M. Roux, et des bourses que le Conseil municipal a fondées à l'Institut Pasteur en faveur d'hommes pleins de mérite. Veuillez agréer, Monsieur le Président, l'assurance de ma haute considération. "PASTEUR."

Ambulatory Delirium.

In the *Gazette des Hôpitaux* of July 2nd there appears a communication from Professor Raymond, the late regretted Professor Charcot's successor, on the above-named curious malady, to which he gives the supplementary denomination "fugue." He points out that the condition is not part and parcel of amnesia, or even a consequence of it. In retrograde localised amnesia, due, for example, to an injury, the events of the forgotten period are ordinary occurrences, whereas the acts characterising the fugue are quite special. What imparts to ambulatory delirium a special "*cachet*" is the association of certain cardinal symptoms, the most important of which are three in number. They are: 1. An irresistible impulse to perform certain acts. In a case quoted it impelled the patient to walk, to undertake journeys; but the impulse may take some other channel of expression. 2. The act, whatever form it may take, is accomplishable in an intelligent manner; in other words, the movements are regular, coördinated, and in harmony with surrounding circumstances. The patient does not fall nor does he stumble against obstacles. He even does not omit to pay for his railway ticket. 3. The impulsive act performed, there is complete forgetfulness of the total period covered by the said act. The fugue may accordingly be defined as an impulsive, complicated, and quite coördinated act followed by amnesia. These impulsive acts, or fugues, may be met with in three different disorders—viz., epilepsy, hysteria, and in the *dromomania* of Régis. May they not also occur in senile dementia? Only last Wednesday afternoon an aged patient of mine inhabiting the Victoria Home, Neuilly, wandered away, bonnetless, and, discovered the same night by a policeman on a bench at Batignolles, some miles away, was forthwith lodged at the Prefecture of Police, where she remained until discovered by us on the Friday afternoon. Questioned by me on Friday at the home, she assured me that she had never left her room. Her memory is a complete blank as to the events that occurred during her two days' absence from home. This poor old Englishwoman had lived in Paris for over thirty years, and was well acquainted with the topography of the city.

A Dental School at Bordeaux.

It is intended to create at no distant date at Bordeaux a school of dentistry. The promoters of the scheme are a few local dentists and a group of Doctors of Medicine, most of whom are members of the teaching staff at the Bordeaux Faculty of Medicine.

Medicine and Politics.

Our French *confrères* dabble in politics much more freely than ourselves. There is a fair sprinkling of them in both Houses of Parliament, and Conseils Généraux and municipalities are full of them. Woe to the practitioner who, having imbibed during his university career anti-clerical ideas, establishes himself in practice in a "reactionary" community, and ventilates his advanced and, according to him, enlightened opinions. His existence soon becomes a burden, and unless he be endowed with a thick skin and a long purse he may soon have to seek a more congenial field for the exercise of his profession. Nor are the Republicans more tolerant, as witness the enclosed advertisement culled from the current number of the *Progrès Médical*.

On demande un médecin républicain pour une commune importante du département de la Vendée. Tête de ligne de chemin de fer pour un port de pêche et une station balnéaire. Gare à 2 h. 1-2 de Nantes et à une demi-heure de la mer. Pays de vignobles. Pas de pharmacien. S'adresser à la rédaction du journal, le jeudi de 3 heures à 6 heures.

July 9th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Carcinoma Antitoxin.

THE article communicated by Professor Emmerich and Dr. Scholl to the *Deutsche Medicinische Wochenschrift*, which was mentioned in my letter inserted in THE LANCET of May 4th, was received here with general scepticism. That this feeling was justified is now proved by the published observations of Professor Bruns (Tübingen) and Professor Augerer (Munich). Professor Bruns was quoted by the authors as vouching for the efficacy of the treatment, but he now states that in no instance was a curative effect remarked, whilst in some cases the general state of the patients was very unfavourably influenced. Cardiac trouble and raising of the temperature were very frequent, and must have been due to a septic condition of the fluid. To this suggestion Professor Emmerich answered that the antitoxin was originally aseptic and must have been spoiled by Professor Bruns or his assistants. Professor Bruns replied that the fluid was examined immediately after its arrival in the bacteriological laboratory of the University, and numerous streptococci were found in it. Professor Augerer stated that two of his cases were attacked with real erysipelas during the antitoxin treatment. The controversy between Professor Emmerich and his opponents sometimes assumed a very personal character and continues to fill the columns of the medical papers. The general impression is that the real carcinoma antitoxin has not yet been discovered.

The Annual Meeting of the German Practitioners' Association.

This meeting was held on June 28th and 29th in Eisenach, under the presidency of Dr. Aub (Munich). As probably your readers are not acquainted with the organisation of the Practitioners' Association (Deutscher Aerztevereins-Bund) it is right to explain that it has no scientific objects, but was founded in order to improve the social condition of the profession. The association, like the British Medical Association, consists of district branches whose delegates meet every year and form the "Deutscher Aerztetag." At these meetings questions of general professional interest are discussed, especially those concerning the relations between medical men and the public. The delegates have as many votes as they represent members, and the district branche, salthough independent, are required to observe the decisions of the meeting. There is also a council elected annually, which meets from time to time to prepare the business of the general meeting and to deal with urgent questions. The institution has no official character, but depends entirely upon the voluntary agreement of the individual urban and district branches. The meeting was opened by the chairman, Dr. Aub, who in his introductory address pointed out that the workmen's insurance laws, by which every workman was compelled to become a member of a sick-club, had materially affected

Digitized by Google

some departments of medical practice. Individual practitioners being powerless to struggle against the predominancy of the clubs, it becomes the duty of every medical man to join his district association, when he will be supported against any unjustifiable pretensions of the sick-club committees. Another matter of importance, which requires the close attention of the representatives of the profession, is, in Dr. Aub's opinion, the obvious deficiency of the qualifying examinations. For instance, a knowledge of mental diseases, which is not required by the existing regulations, ought to be regarded as a necessity for every practitioner. Alluding to the Mariaberg Asylum trial, the chairman said that a lack of knowledge of this branch of medicine had unfortunately caused medical men to appear at a disadvantage in the courts of law. After this introductory speech the secretary reported that the association had now 249 district branches, with 14,139 members, and that 117 delegates, representing 13,407 medical practitioners, were present at the meeting. The first subject discussed was the so-called "free choice" system (freie Aerztewahl), which I explained in THE LANCET of Feb. 2nd, 1895. According to this system, a sick-club does not appoint a fixed number of medical officers, but any practitioner of the district who agrees to the club terms is allowed to attend the members. There are only a few places where this system is still in operation, but the desire to have it adopted everywhere is very strong, not only in the profession, but also among the working men, the latter, of course, wishing to exercise the right of selecting the medical attendant in whom they have most confidence. The principal opponents of the new system are the specially appointed medical officers, who fear that they will lose much of their income if the fees paid by the clubs are distributed among all the practitioners of the place. The opinion of this meeting, where very numerous adherents of both the old and the new system were present, was therefore anxiously awaited. After a very long and sometimes heated debate the following motion was adopted: "That this meeting is of opinion that the free choice system is the most satisfactory both to the profession and to the club members, and that it is therefore desirable to have this system accepted throughout the empire; that, in order to avoid unjustifiable demands on the part of club committees, the contracts with the clubs ought to be made, not by the individual practitioner, but by the district branches of the association." A contrary motion, proposed by Dr. Windels, to the effect that the free choice system, although theoretically preferable, would lead the clubs to ruin, was rejected by an immense majority. On the second day the meeting discussed the mutual relations between medical practitioners and insurance companies. Several anomalies exist in these relations and ought to be abolished. In some companies, for instance, it is usual for the insurance agents to appoint the medical officers for the companies. At a joint conference of the council of the Practitioners' Association and the managers of the insurance companies it was agreed: (1) That the medical officers shall be appointed by the managers only and not by the individual local agents; (2) that the medical examination shall take place in the consulting-room of the medical man and not in the house of the proposer; (3) that the results of the examination shall be kept strictly secret; (4) that a fee of at least ten marks shall be paid by the company for every examination; and (5) that a permanent commission, consisting of medical men and insurance officials, shall be instituted in order to settle disputed questions. In the discussion it was stated that some medical men had been made liable to legal prosecution because they had given information as to the health of a proposer's relatives without having previously obtained their permission. It was thereupon decided that the companies should arrange these matters with the families before applying to their medical officers for a certificate. All the other propositions of the council were unanimously adopted. The next meeting will be held at Nuremberg.

June 9th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Italy out of Town.

"TWO voices are there, one is of the sea, One of the mountains," sings Wordsworth in a magnificent sonnet, and all Italy, professional or lay, is divided as to which it shall respond to. There is so much that is to be said for either that many will declare for both—if Romans, alternating between the Sabine or Alban Hills and Porto d'Anzio; if Neapolitans, between Capo di Monte and Sorrento; if Tuscans, between Vallombrosa and Viareggio. Italy, indeed, suffers from an *embarras de richesses* of summer haunts, and nothing but her backward hotel enterprise explains the fact that she does not detain on her uplands or on her seaboard the thousands of winter residents who would gladly avoid the Swiss tourist hive or the Tyrolese ant-hill. But she must take not one, but many leaves out of the Helvetian hotel-book before she can keep the visitors she attracts, and particularly on the less familiar lines of travel she must bring her cuisine and her accommodation, above all her drainage and her water-supply, out of the rut of mediæval tradition if she is to spare herself the mortification of witnessing the paying public deserting her picturesque, historic towns for Swiss hamlets which are neither and have not even the advantage of more invigorating air. No British practitioner in her more frequented winter cities but has lamented the sad necessity he has been under of sending his convalescents, often at great risk and greater expense, "over the watershed," when Nature was literally holding out her hands to detain them, and nothing but the rough, sometimes revolting, hotel appointments frustrated her kindly invitation. Improvement is, indeed, manifest in some of the provinces; but, in Mr. John Morley's phrase, the pace is "killingly slow," and we shall be well into the twentieth century before Italy returns to the social refinements and attractions even of Baiæ or Præneste in the first.

A Mixed Blessing.

This, as THE LANCET[1] has pointed out, is a proper characterisation of the introduction of the new remedy for diphtheria so successfully practised in many a European city. It has had the effect of paralysing that hygienic or sanitary movement which, in these centres, was just beginning to combat the diphtheritic poison at its source. By the opportune injection of the "siero difteritico" a Roman child well-nigh moribund from the disease was the other day rescued in the most striking manner, and the names of the physicians in charge of the patient received an attention which these able practitioners would gladly see bestowed on the faulty health conditions to which the little patient owed his malady. But the old adage, "Prevention is better than cure," is a plant of tardy growth in a semi-superstitious society, where the prestige of a "sovereign remedy" will always countervail the humbler calls of sanitary observance. Happily "igiene locale" has been vigorously taken up by the communal Giunta and a "regolamento" formulated for Rome and its province which will shortly be extended, on express application, to 150 other communes throughout the kingdom.

The Health of the Pope.

After nearly ten months of in-door life, His Holiness has resumed of late his saunter in the Vatican Gardens—that spacious and beautifully disposed expanse of wild wood and flower bed which slopes gently uphill from behind the Palace to the ridge of the Janiculan. The frequent fountain, "shaking its loosened silver in the sun," the winding watercourses "still murmuring, as they run, to the hushed ear of noon," are not less grateful to sense than to respiration, from the delicious coolness they impart under the vertical heat. After threading his favourite walks in this "maze of amenities," as it has been called, the Holy Father retires to the tower of Leo IV., recently adapted as a summer retreat by the architect Vespignani, from whose able hands it passed into others not less able in the department of internal decoration and appointments. There the supreme Pontiff can, on occasion, give audience to the high functionaries of his court; there he can spend the forenoon and afternoon in study and *siesta* with a degree of comfort that prompted the suggestion that he might have sleeping apartments fitted up in the tower as well. But the project found no favour with the medical advisers who keep watch over his person, the Mons Vaticanus still retaining through the hours of night that character for insalubrity it received from the Augustan poets. So before sunset Leo XIII. is conveyed back to the Palace and up the successive flights of stairs in his *sedia gestatoria* to the traditional dormitory of his predecessors. How well the life he now leads is suiting him may be inferred from the fact that not for many months has the august octogenarian been more vigorous in mind or body. Indeed, no

[1] THE LANCET, Jan. 12th, 1895, "Sero-therapy and Sanitation."

Digitized by Google

later than the 4th inst. he gave an audience, at the close of the day, to Don Paolo Rossignoli, the missionary hero who effected so romantic an escape from the dungeon of the Mahdi—an audience which lasted nearly an hour, during which His Holiness, after listening attentively to his guest's thrilling narrative, examined him minutely as to the progress of the Roman Catholic missions in Upper Egypt, and having elicited from him much valuable information imparted the Apostolic benediction with quite unusual fervour.

The Origin of the Red Cross.

Italians have always claimed priority in conceiving and formulating those proposals for the international care of the wounded in war which culminated in the Geneva Convention. True, the French d'Arrault published on June 10th, 1861, his "Notice sur le Perfectionnement du Matériel des Ambulances Volantes," and the Swiss point complacently to their countryman Dunant's "Un Souvenir de Solferino," which, however, is dated 1862. But there is no doubt that before the former of these Professor Palasciano of the Naples Medical School read on April 28th, 1861, before the Accademia Pontaniana his "La Neutralità dei Feriti in Tempo di Guerra," in which, with arguments at once humanitarian and technical, he called on belligerent Powers to recognise on the battlefield a reciprocal neutrality in aid of the wounded, so as, by the greater efficiency of relief, to diminish the number of fatal cases among those who had to undergo amputation, and to withdraw from the necessity of amputation those on whom conservative surgery might be practised. Professor Palasciano, moreover, not content with enunciating the principle, developed, on Dec. 29th following, before the same Accademia, the following scheme for securing the neutrality desiderated: (1) That the belligerent armies should reciprocally give up all their wounded prisoners immediately after battle; (2) that all the wounded who could not be given up should be treated medically in the places occupied by the respective ambulance corps; and (3) that the ambulance corps should be furnished with a safe-conduct to pass the hostile frontiers and to remain there as long as required by their attendance on the wounded. Professor Palasciano continued his humane propaganda in every possible way, especially in his journal, begun after 1866 entitled "Archivio di Memorie ed Operazioni di Chirurgia." It was, in truth, a logical sequence of this propaganda that gave rise to the Geneva Society, which, after the International Congress of 1863 culminated in the Geneva Convention of Aug. 22nd, 1864. Out of this grew the Committee of the Red Cross, having its seat at Geneva, to which branches are affiliated from nearly every civilised nation in the world. In commemoration of Professor Palasciano's beneficent life-work a monument has just been unveiled to him in the Campo Santo at Naples, the spokesman of the occasion being Professor Pasquale Fiore, whose eloquent discourse insisted on the above facts and on many others in illustration of them before a distinguished audience, chiefly medical. The monument, a fine work of art, is of granite, and consists of a tomb, on which rises a great marble cross inscribed with the words: "Quod Deus conjunxit, homo non separet" (What God hath joined, let not man put asunder).

The Waters of San Genesio.

The Turin Medical School, mainly in its clinical and therapeutic departments, was largely represented the other day in an expedition to the source of San Genesio. From 1824 these waters were styled Fonte Regia from their proved efficacy in the case of more than one member of the Royal House of Savoy. In chemical quality they were classified as "saline-iodobromo-sulphurous," and as such they continued in much request. In 1870 an addition to the attractions of the spot was made by the discovery of a new spring classified as "ferrugino-alkalino-bromide," in which, by means of spectrum analysis, the Cavaliere Celestino Bonelli of Turin found a considerable proportion of lithia. The excursion party was formed to report upon the improvements effected in the balneary service and appointments as well as in the accommodation at San Genesio and the entertainment afforded to the invalid public. The result of the visit was altogether satisfactory, an impression which found eloquent voice in the after-dinner oratory of more than one distinguished professor of the sub-Alpine University, conspicuous among whom were Dr. Cesare Lombroso, the Lecturer on Animal Anthropology, Professor F. Porro, the eminent physicist, who holds the chair of Astronomy, and the well-known analyst the Cavaliere Bonelli.

The Health of the Kingdom.

The Consiglio Superiore di Sanità has just received the Commendatore Pagliani's report for the first *semestre* of the current year. The "condizioni sanitarie" are described as "relativamente buone." There were a few cases of small-pox, but whenever the malady declared itself it was promptly met, thanks to the efficacious measures at once set on foot by the Minister of the Interior. Professor Pagliani concludes by remarking that the "public health, satisfactory in the past *semestre*, represents a state of things which is steadily improving. Not only is the mean of 'morbosità' declining, above all in the infective diseases, but also the mean of the 'mortalità,' which marks a still more pronounced diminution."

July 7th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Suicide and Crime in Russia.

PROFESSOR SIKORSKI of the University of Kief, writing in the *Kievlianin* upon the psychology of the Russian people, brings forward some interesting statistics concerning the frequency of suicide in the different nations of Europe. According to these figures the death-rate from suicide per million living is in Saxony 311, in France 210, in Prussia 133, in Austria 130, in Bavaria 90, in England 66, while in Russia it is as low as 30. Further, it is found that during the last thirty years the suicide-rate has in Russia remained stationary, while in all other European countries it has increased by 30 or 40 per cent. The exact significance of figures such as these, relating to so complex a phenomenon as suicide, is not easily brought out. Few, however, will be disposed to question the assertion that much of the explanation of the low rate in Russia is to be found in the patience and long-suffering of the Russian peasant under even the worst misfortunes. Among other characteristics Professor Sikorski also finds a certain indecision of character which fears to say a word or do an action which shall not admit of retreat or withdrawal. Crime is comparatively rare in Russia; thus, the number of persons tried for murder per million living in the year 1887 was in Italy 96, in Spain 55, in Austria 22, in France 15, in Russia 10, in Germany 9, and in England only 6.

Cholera.

Little has been heard of cholera in this country during the present summer. For many weeks past the only district in which the disease has been present has been the government of Volhynia. The latest returns from there are as follows: from May 14th to 20th, 42 cases and 9 deaths; from May 21st to 27th, 37 cases and 11 deaths. (The dates mentioned are Old Style dates.) St. Petersburg is so far free from cholera. In 1892 the earliest cases here were at the end of July; in 1893 the disease reappeared early in August; and last year it began as early as June 8th (20th).

The Government and the Harvesters.

A commission was recently appointed to inquire into and regulate the movements of peasants who leave their own districts to find harvest work in other and distant districts. The commission is appointed mainly with an economical object—the distribution of the labourers with the greatest advantage both to the labourers themselves and to the local requirements of the harvest. Some control, however, of this great annual movement of peasants should be of benefit from a public health point of view. Every year many thousands, attracted by the richer harvests of the south and east, have left their homes and, hitherto without any control, have made their way in those directions. Only too often they have found the market already overstocked and have had to return home destitute, although at the same time in other districts there was a dearth of labourers. Apart from this waste of force, the uncontrolled movement of so many peasants has been a fruitful means of spreading diseases. Among these syphilis holds perhaps the first place. Every year the report of the Medical Department brings forward evidence of this. I have already quoted the striking instance of one peasant who returned to his village and in the course of a few months infected with syphilis, which he contracted while

Digitized by Google

away, no less than twenty-three people. It is the same with zymotic diseases, the most striking example of which was the cholera epidemic of three years ago, which was largely spread by these "migrant labourers." The commission consists of representatives of the Ministries of the Interior, of Agriculture and Imperial Domains, of Finance, of Justice, and of Ways and Communications.

The Giliaks.

In my last letter I gave a short account of the Siberian tribe of Buriats. The following notes, relating to a still smaller tribe, the Giliaks, are from a Siberian newspaper (the *Tobolsk Government News*). The race appears to be rapidly dying out; there are now only some 3000 of them living. They are found in the island of Sakhalin (the penal convict island of Russia in the Pacific) and along the banks of the river Amur. Like the Buriats they smoke and drink inordinately. For *vodka* a Giliak will sell anything—his wife, his daughter, his sister, his mother, and even the bear which he looks upon as a god. Drink and syphilis are rapidly exterminating the race, and the end is hastened by the barbarous treatment of their women in childbed. When labour begins the woman is taken to a rapidly prepared shed, and is there left absolutely alone until all is over. In summer this may perhaps matter little, but in the intense cold of a Siberian winter it often happens that either mother or child dies, and sometimes both. Their religion consists solely of the worship of the bear. Young bears, it is said, are caught alive and carefully fed until they attain maturity; they are then led out into the woods at night time, and by the light of bonfires and with much singing and dancing are slaughtered. The flesh is torn from their bones and, while still smoking, eaten by the Giliaks, who look upon it as holy food. Altogether, the picture of these remote Siberian tribes is not an inviting one.

St. Petersburg, June 24th (July 5th).

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Insanity in New South Wales.

THE annual report of the Inspector-General of the Insane in New South Wales has just been published. On Dec. 31st, 1894, the number of insane persons on the register was 3587, as against 3425 at the close of 1893, or an increase of 162 during the past year, which is very much above the average for the past twenty years. The chief factor in the production of this increase has been the general commercial depression, which has operated in two ways: first, by directly producing insanity, especially in the neurotic and weak-minded, who are handicapped in the race when the conditions of life are more than usually hard; and, secondly, by obliging persons, formerly able and willing to support idiot children and imbecile relatives of older years, to throw them upon the charity of the State. The proportion of insane to population, which in 1893 was 1 in 357, had at the close of 1894 risen to 1 in 348. The total number admitted was 712, and of these 644 were admitted for the first time. The discharges numbered 350, and of these 296 had recovered and 54 were relieved so far as to permit of their being left in the care of relatives. The recovery and death rates compare very favourably with the returns from institutions in Great Britain. For the first time for twenty-eight years the whole of the patients at the charge of the Government are housed within the wards of its own hospitals. The average weekly cost for maintenance was 10*s.* 7*d.*

Medical Practitioners Bill for New South Wales.

The Bill for the registration of medical practitioners and imposing penalties on any unqualified person who assumes any title implying that he is a legally qualified medical practitioner, has been considered in committee in the legislative assembly and passed its second reading.

New South Wales Medical Union.

From the report of the New South Wales Medical Union, read at the annual meeting of that association, it appeared that 46 new members had been elected during the past year, and there were on Feb. 28th, 1895, 127 members. Several cases had been considered. In the case of the late Dr. Struthers *v.* White the defendant apologised and withdrew all charges, and paid all costs. In the case of Hull *v.* Dr. Cummings the jury found for the defendant. Another case was still *sub judice*. The election of office-bearers resulted as follows:—Trustee: in place of Dr. C. Dagnell Clark Dr. T. Fiaschi. Hon. Treasurer: Dr. W. H Crago. Joint Hon. Secs.: Drs. A. Jarvie Hood and G. Lane Mullins. Members of Council: Dr. G H. Macswinney, Mr. J. Foreman, Dr. A. MacCormick, Dr. S. T. Knaggs, Dr. P. J. Collins, Dr. R. Scot-Skirving, Dr. E J. Jenkins, Mr. B. J. Newmarch, Dr. R. L. Faithfull, and Mr. P. M. Wood.

Action against a Private Hospital.

A case of some interest to the profession was recently tried in Melbourne. The plaintiff, Mr. C. J. Carter, sued Miss Macartney for negligent treatment while an inmate of the defendant's private hospital. Mr. Carter was originally a patient in the Melbourne Hospital, suffering from typhoid fever. Abscesses then formed in many places and were opened and drained. He went home and then went into Miss Macartney's private hospital, where other abscesses were opened and drained, and it was alleged that a drainage-tube three inches long was left in one of the wounds, which closed over the tube. He returned to the Melbourne Hospital, where the tube was extracted. He claimed £500 damages. For the defence it was stated that no incision was made in the right thigh (from which the tube was extracted) during his stay at Miss Macartney's hospital, and that there was no negligence in nursing there. The judge said the plaintiff had proved negligence, and gave a verdict for £25.

Gynæcological Cases.

The current number of the *Australian Medical Journal* is characterised by the number of cases of gynæcological interest it contains. Mr. F. D. Bird records two cases. The first was a suppurating ovarian hydrocele, the diagnosis of which was puzzling, the symptoms coming on suddenly and simulating appendicitis at one time and intestinal obstruction at another. When the acute symptoms had subsided laparotomy was performed and the cyst removed. The patient made a perfect recovery. The second case was one of ovarian abscess, admitted with symptoms pointing to perforative peritonitis and in a state of collapse. Laparotomy was performed a month after admission, and the condition found to be salpingitis, with an abscess in the ovary, a leakage from which, it was assumed, was the cause of the acute symptoms. Mr. W. Moore records three cases. The first was a case of ovarian hydrocele, the second was an abscess in the ovary, and the third salpingitis with adhesions. Laparotomy was successfully performed in each case. Dr. James A. Reid records three cases. Two were tubal pregnancies, one ruptured, and the other unruptured. The first case died from intestinal obstruction after laparotomy attributed to a kink in the bowel; the second case recovered. Dr. Reid inquires whether a tubal fœtation is ever arrested in its growth and absorbed without going on to rupture or suppuration. In his second case the growth had apparently come to a standstill about the sixth or seventh week of its life, and at the eleventh week showed no evidence of any tendency to rupture. Dr. Reid also reports a case of complete prolapse of the uterus, vagina, bladder, and rectum treated by hysterectomy and perineorrhaphy, and complicated by hydronephrosis due to calculi blocking the right ureter, but at first suggesting ligature of the ureter during the operation. At the last meeting of the Victorian Branch of the British Medical Association gynæcology was again *en évidence*, Dr. Felix Meyer reading Notes on Six recent Cases of Abdominal Section. Two were for uterine fibro-myoma, one for ovarian cyst, one for pelvic peritonitis, one for cyst of the broad ligament, and one exploratory, the condition found being a pregnant uterus with fibro-myoma.

Case of Carcinoma of Perineum and Urethra.

Mr. G. A. Syme records a case of growth in the perineal region associated with urinary fistulæ and following an injury received ten years before. The growth occupied the perineum, blocked the urethra, and projected into the rectum. Microscopic examination showed that it was an epithelioma.

Appointment.

Mr. C. P. B. Clubbe has been appointed surgeon to the Prince Alfred Hospital, Sydney, and Lecturer on Clinical Surgery at the Sydney University, in place of Mr. Twynam, resigned.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on Thursday, the 4th inst. :—

Anatomy and Physiology.—Arthur Henry Michael Saward, Oswald Marriott, Albert Henry Beaumont Kirkman, William Pennington Grellet, Vincent James Crawford, Arthur Richard Thomas, John Edward Powell, and Arthur William Nourse, Guy's Hospital; Penry William Rowland, Llewelyn Arnold Baiss, and Cyril Pinchard Burd, St. Bartholomew's Hospital; Guy Hemming Coltart, Westminster Hospital; Henry Herbert Johnson Edwards, Hugh Campbell Ross, Hugh Basil Greaves Newham, and Edward Ernest Nicholl, St. Thomas's Hospital; William George Porter and James Warburton Brown, Charing-cross Hospital; Vernon Cyril Bensley, St. Mary's Hospital; and Alexander Mercer, University College, London.

Anatomy only.—Sidney Herbert Mason, Guy's Hospital.

Fifteen gentlemen were referred in both Anatomy and Physiology.

Friday, the 5th inst.:—

Anatomy and Physiology.—John Haselwood Roberts, Charles Deane Outred, Charles Bertram Thomson, Thomas Hamlyn Whittington Landon, and William Langworthy Baker, Guy's Hospital; Arthur Ruscombe Crane Parsons, King's College, London; Frank Horridge, George Ernest Gask, and Richard Strike Flemying Hearn, St. Bartholomew's Hospital; David Davies and Samuel Lee Craigie Mondy, University College, London; William Frederick Willis, George Arnold Hutchinson, and Henry Thomas Mann, St. Mary's Hospital; Stanley Arthur Lucas, Cambridge University and St. Thomas's Hospital; James Herbert Robinson, Charing-cross Hospital and Mr. Cooke's School of Anatomy and Physiology; Herbert Wortley Fisher, London Hospital; and Arnold Saxty Good, St. George's Hospital.

Eighteen gentlemen were referred in both Anatomy and Physiology.

Monday, the 8th inst. :—

Anatomy and Physiology.—Frederic Hasler and Evelyn Kempson Brown, London Hospital; Edward Erratt Parrett and Kenneth Bush Alexander, Guy's Hospital; Thomas Denman Dawson and Howell Davies, St. Bartholomew's Hospital; Charles Edward Fenn and George Oliver Pierce, King's College, London; Charles Ernest Turner, University College, London; Percy Gardiner, Middlesex Hospital; and Philip Dare Cogswell, St. Mary's Hospital.

Anatomy only.—Geoffrey Stuart Moore, London Hospital and Mr. Cooke's School of Anatomy and Physiology.

Physiology only.—Edgar Curnow Plummer, King's College, London; Francis Ryalls Eddison, St. Bartholomew's Hospital; Edward Simpson Shave and William Walton Claridge, Middlesex Hospital; and Henry Priest Shanks, University College, London.

Nineteen gentlemen were referred in both subjects, five in Anatomy only, and one in Physiology only.

Tuesday, the 9th inst:—

Anatomy and Physiology.—Edmund Frederick Rose, St. Bartholomew's Hospital.

Anatomy only.—James Michael Aloysius Manning and Charles Nugent Chadborn, St. George's Hospital; Winstan St. Andrew St. John, St. Mary's Hospital; Frederick Arthur Johns, London Hospital; Lanyon Edward Owen, University College, London; Cyril Cecil Poole, Guy's Hospital.

Physiology only.—John James Cecil Hamilton, King's College, London; Charles Arthur Craven Salmon, Guy's Hospital; Frank Voller, St. Thomas's Hospital; Alfred Edward Seller, London Hospital; Frederick John Waldmeier, Syrian Protestant College, Beyrout, and London Hospital.

Four gentlemen were referred in both subjects, four in Anatomy only, and four in Physiology only.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates passed in the Primary Examination, Part I., July, 1895 :—

Chemistry.—F. R. Greenwood, St. Bartholomew's Hospital; and E. C. Scarlett, Royal Free Hospital.

Materia Medica and Pharmacy.—C. E. C. Child, Charing-cross Hospital; L. T. Lavan, St. Bartholomew's Hospital; E. E. H. Madden, Royal Free Hospital; G. H. Williams-Parry, Sheffield; A. Ross, Guy's Hospital; and C. H. Thomas, London Hospital.

Primary Examination, Part II. :—

Anatomy and Physiology.—M. E. Bennett, Royal Free Hospital; G. E. Brooke, Cambridge and London Hospital; H. J. Clutterbuck, Middlesex Hospital; A. M. Edey, Sheffield; T. A. E. Fawcett, Leeds; C. L. Francis, St. Bartholomew's Hospital; C. Franks, Westminster Hospital; G. C. Hobbs, St. Bartholomew's Hospital; W. E. G. Maltby, St. Bartholomew's Hospital; H. D. Matthews, Middlesex Hospital; C. Powell, Cambridge and St. Thomas's Hospital; B. G. Roscoe, Manchester; and C. H. Thomas, London Hospital.

Anatomy.—W. F. E. Ashton, Birmingham; G. F. Beacher, Sheffield; H. J. De Saram, Middlesex Hospital; E. P. Marett, St. Thomas's Hospital; G. L. Meredith, London Hospital; H. Morris, St. Bartholomew's Hospital; and G. Parnell, Charing-cross Hospital.

Physiology.—T. H. Bailey, King's College; F. E. Bissell, Birmingham; M. Caldwell, Dublin; R. F. W. Crawford, St. George's Hospital; G. A. Crowe, London Hospital; G. W. Dutton, Middlesex Hospital; M. B. Hebron, King's College; C. E. Hibbard, Guy's Hospital; B. Hogan, London Hospital; H. M. Maitland, Royal Free Hospital; S. J. Meredith, Birmingham; C. E. Proctor, Liverpool and Edinburgh; F. L. Roper, Dublin; E. G. Smith, Westminster Hospital and London Hospital; W. A. Sugden, St. Mary's Hospital; and D. L. Thomas, Birmingham.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bordeaux:* MM. Cannieu and Pachon have been appointed *professeurs-agrégés* of Anatomy and Physiology respectively.—*Lyons:* MM Siraud and Durand have been appointed *professeurs-agrégés* of Anatomy, and M. Doyon *professeur-agrégé* of Physiology.—*Melbourne:* Dr. F. D. Bird has been appointed Lecturer on Surgery.—*Montpelier:* MM. Mouret and Delezenne have been appointed *professeurs-agrégés* of Anatomy and Physiology respectively.—*Palermo:* Drs. Mirto, Ficano, di Blasi, and Foderà have been recognised as *privat-docenten* in Psychiatry, Laryngology, Hygiene, and Pharmacology respectively.—*Nancy:* MM. Jacques and Lambert have been appointed *professeurs-agrégés* of Anatomy and Physiology respectively.—*Naples:* Drs. Jappelli, Baculo, Costabile, and Screvini have been recognised as *privat-docenten* in Physiology, General Pathology, Pharmacology, and Odontology respectively.—*Paris:* M. Thiéry has been appointed *professeur-agrégé* of Anatomy.—*Prague* (German University): Dr. von Wunschheim has been appointed *docent* in Pathological Anatomy. Dr. Hugo Rex, Dr. J. Pohl, and Dr. Steinach have been promoted to Extraordinary Professorships of Anatomy, Pharmacology, and Physiology respectively.

MEDICAL MAGISTRATES.—Mr. William Evans, L.R.C.P. Edin., M.R.C.S., of Llanerchymedd, has been placed on the Commission of the Peace for the County of Anglesey.—Mr. R. D. Evans, M.R.C.P., L.R.C.S. Edin., of Llysmeddyg, Blaenau-Festiniog, has been placed by the Lord Chancellor on the Commission of the Peace for Merionethshire.

PRESENTATION.—Mr. Hugh Lewis Hughes, L.R.C.P. & S. Edin., Dowlais, was on the 14th ult. presented with a massive solid brass timepiece, together with a pair of candelabra to match, elegantly designed and bearing the inscription: "Presented to Dr. Hughes by the members of the Women's Ambulance Class, Dowlais, June 14th, 1895." This is the sixth occasion on which the local members of the St. John Ambulance Association have shown their appreciation of his labours as surgeon-instructor.

BEQUESTS AND DONATIONS TO HOSPITALS.—Sir Donald Currie, M.P., has sent a donation of £100 towards the Royal Infirmary, Newcastle-upon-Tyne, as a memento of his recent visit to that borough.—The late Mr. Thos. R. Harding of St. Ann's Tower, Leeds, has bequeathed £100 to the Leeds General Infirmary.—A legacy of £36,236 has been received by the Court of Governors of the London Hospital from the late Mr. W. A. Gursden.—Mr. John E. Davies, late of Park-street, Bristol, has bequeathed £200 to the Bristol Hospital for Sick Women and Children.—The late Mrs. A. T. Hall of Lowndes-square, London, has bequeathed £20,000 to St. George's Hospital, Hyde-park-corner, in memory of her late husband, Major Hall.—Mr. John Howarth Ormerod, late of Beechwood, Birkdale, has bequeathed (free of legacy duty) £1000 to the Halifax Infirmary.—The last Sheffield Hospital Sunday Fund collection, which amounted (after paying expenses) to £1941 8*s.* 10*d.*, has been apportioned as follows:—The Sheffield General Infirmary, £1073 10*s.* 7*d.*; the Royal Hospital, £462 8*s.* 11*d.*; the Jessop Hospital, £296 10*s.* 2*d.*; and the Children's Hospital, £108 19*s.* 2*d.*—Lady H. M. R. Robinson, late of Penzance, has bequeathed £500 to the Royal Hospital for Incurables.—The trustees of Smith's (Kensington Estate) Charity have granted a donation of £500 to the special fund now being raised for St. Thomas's Hospital, London; and the Corporation of the City of London has voted 200 guineas towards the same fund.—A gift of £1000 has been received by the treasurer of the Royal Hospital for Diseases of the Chest, City-road, London, from a lady who does not wish her name to be announced.—The Great Northern Central Hospital, London, has received a further grant of £400 from the trustees of Smith's (Kensington Estate) Charity.—The late Mr. John Hughes of Liverpool has bequeathed £300 to the Liverpool Eye and Ear Infirmary, £200 each to the Liverpool Royal Infirmary and the Liverpool Royal Southern Hospital, and £100 to the Stanley Hospital; and after the decease of Mrs. Hughes the following bequests are left—viz.: £500 each to the Liverpool Eye and Ear Infirmary, the Liverpool Royal Infirmary, and the Royal Southern Hospital, Liverpool, and £250 to the Stanley Hospital.—The treasurer of the Dundee Royal Infirmary has received a donation of £1540 from Mr. James Key Caird, being the amount of the deficit on the last year's accounts.

DURING the meeting of the British Medical Association the President and Fellows of the Obstetrical Society of London intend to give a banquet at the Whitehall-rooms on Friday, Aug. 2nd, at 7 P.M., in order to entertain distinguished foreign obstetricians and gynæcologists.

VACATION COURSES IN BELGIUM.—Some of the Belgian universities are making arrangements for vacation courses for practitioners to be held in the month of September. These will be of the same character as the well-known courses in the German universities, and may be useful to English practitioners who want a little insight into Continental methods, especially if their knowledge of French happens, as is frequently the case, to be far better than their knowledge of German. Brussels, Liége, and Ghent are opening their doors this summer for vacation courses, but up to the present Louvain appears to be holding aloof from the movement.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Close of the Session and the Parliament.

On Saturday, July 6th, the work of the session was brought to a close, and the prorogation took place, and on Monday, July 8th, the Parliament was dissolved by Her Majesty the Queen, acting on the advice of the Marquis of Salisbury.

Weights and Measures.

The Select Committee of the House of Commons appointed to inquire into and report upon our system of weights and measures has recommended that the metrical system be at once legalised for all purposes, that after a lapse of two years it be rendered compulsory by Act of Parliament, and that the system be taught in all public elementary schools as a necessary and integral part of arithmetic, and that decimals be introduced at an earlier period of the school curriculum than is the case at present.

HOUSE OF LORDS.

FRIDAY, JULY 5TH.

Factories and Workshops Bill.

In order to get the Factories and Workshops Bill passed into law before the close of the Session their lordships suspended the standing orders of the House and took all the stages of the Bill at this sitting. On the second reading stage there was a debate of considerable length.

The Marquis of Ripon, in moving the second reading, said that the Bill introduced no new principle, but simply extended the existing factory legislation. In these days, when every one felt so great an interest in all matters connected with sanitary legislation, and when sanitary science had advanced so much and impressed itself so strongly on the mind of the public and Parliament, he felt confident that there were no members of the House who would object to make the provisions of factory and workshop legislature more stringent and more complete in respect to sanitary matters so as to secure the safety of the workers. There was one provision which would specially commend itself, and that was the provision for the imposition of a penalty for allowing wearing apparel to be made up in places where there was any infectious disease. There was another provision which prohibited children from being engaged in the cleaning of machinery in motion. There were also provisions for the maintenance of a register of accidents, which he was quite sure all their lordships would approve. In attempting to pass the Bill, he must depend, of course, upon the new Government, and he appealed to the members of it in the House to give him their aid.

The Marquis of Salisbury said that the Bill belonged to a class which had always been received with great favour in this House, and he agreed that our experience of the Factory Acts was such as to make it desirable to extend their principles as far as we could do so with success. He had nothing to say against this Bill, except to express some slight apprehension with regard to the provisions affecting laundries. He was afraid it would aid the tendency to crush out the smaller industries in this country.

Viscount Cross, speaking as the Minister who was responsible for what was now the principal Act affecting factories and workshops, said that the Act had stood the test of twenty years, and had been the charter of all workmen in factories and workshops.

After some further discussion the Bill was passed through its various stages in exactly the form in which it left the House of Commons.

Fatal Accidents Inquiries (Scotland) Bill.

There was also some discussion before this Bill was passed. Lord Balfour of Burleigh, the new Secretary for Scotland, intimated that it had his approval. He thought it desirable that inquiries into accidents occurring in industrial employments in Scotland should no longer be conducted in secret, although he did not altogether feel confidence in the method of inquiry proposed in the Bill.

HOUSE OF COMMONS.

THURSDAY, JULY 4TH.

The Case of Dr. Cornelius Herz.

On the order for the second reading of the Extradition Bill, Sir Edward Reed said that, while the measure was understood to be intended to meet the case of Dr. Cornelius Herz, it would be of no use in that case unless it contained a provision enabling an accused person to be tried, although not present in court.—Sir Albert Rollit explained that during the period that Dr. Herz had been in England his health had so declined that unless the hearing of his case could be taken in a private residence the Bill would not benefit him.—Mr. Asquith said that undoubtedly the Bill had been suggested to the late Government by the case of Dr. Herz. Without going into the general question of the treatment of Dr. Herz, or the suggestions that he had been subjected to unreasonable espionage, he desired to state that, within the limits which the existing law allowed, the treatment of Dr. Herz, so long as the late Government were responsible in the matter—and he had no doubt it was so still—had been not only humane, but most considerate. Dr. Herz had from first to last been treated with indulgence, and there was no foundation whatever for the statement that, so far as the existing law permitted, he had been subjected to any hardship.

The Bill was read a second time, and at the following day's sitting passed through its other stages.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.

BALLANTYNE, J. W., M.D., F.R.C.P.E., F.R.S. Edin., has been appointed Examiner in Midwifery in the University of Aberdeen.

BEASLEY, J. G., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed a District Medical Officer by the Rowley Regis Urban District Council.

BRIDGES, ERNEST C., M.B., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Great Northern Central Hospital.

BUCHANAN, ROBT. J. MCLEAN, M.B. Univ. Vict., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Assistant Physician to the Liverpool Hospital for Consumption and Diseases of the Chest.

BURTON, A., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to the Addenbrooke's Hospital, Cambridge.

CARVER, E., M.D. Cantab., F.R.C.S. Eng., has been appointed Consulting Surgeon to the Addenbrooke's Hospital, Cambridge.

COCKCROFT, M.D., St. And., M.R.C.S., has been reappointed Medical Officer for the Masham Sanitary District of the Leyburn Union.

ERSKINE, R., M.D., M.Ch. Irel., has been reappointed Medical Officer for the Camborne Sanitary District of the Redruth Union.

GOODMAN, GODFREY, L.R.C.P.I., L.R.C.S.I., L.M.R.C.P.I., has been appointed Medical Officer of Health to the Rural Sanitary District of the Brigg District Council, vice Moxon, resigned.

GREIG, W. C., M.B. and C.M. Edin., has been appointed Honorary Physician to H.B.M.'s Legation at Tangier.

GRIFFITHS, JOSEPH, M.D., C.M. Edin., F.R.C.S. Eng., D.P.H. Cantab., has been appointed Surgeon to the Addenbrooke's Hospital, Cambridge, vice Carver, resigned.

HALPIN, J. E., L.R.C.S.I., L. and L.M.K.Q.C.P.I., has been appointed Public Vaccinator for the Fifth District of the Mansfield Union, vice H. Parry Jones.

HALPIN, J. E., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Medical Officer for the Mansfield Woodhouse Urban Sanitary District, vice Jones.

HINES, JOSEPH, C., L.R.C.S., L.M. Irel., has been appointed Medical Officer for the Burwash Sanitary District of the Ticehurst Union.

JOHNSTONE, E., L.S.A., has been appointed Medical Officer for the Clayton Sanitary District of the Prestwich Union.

KELLY, CHAS., M.D., Lond., F.R.C.P., M.R.C.S., has been appointed Medical Officer of Health to the East Preston Rural Council.

LANGDALE, H. M., M.R.C.S., has been reappointed Honorary Medical Officer to the Uckfield Cottage Hospital.

LUCAS, G., M.R.C.S., has been reappointed Honorary Medical Officer to the Uckfield Cottage Hospital.

MCLEAN, C. J. R., M.D., C.M. Edin., has been reappointed Medical Officer to the Yeadon District Council.

MCWEENEY, E. J., M.D., M.Ch. Irel., has been appointed Analyst to the Richmond District Lunatic Asylum, Dublin.

OLDMAN, C. E., M.D. Cantab., has been appointed Medical Officer of Health for the Godstone Rural Sanitary District.

PECK, E. G., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Queensbury District of Yorks.

PERMEWAN, W., M.D. Lond., F.R.C.S. Eng., has been appointed Honorary Laryngologist to the Royal Southern Hospital, Liverpool.

PHILLIPS, EDGAR V., M.R.C.S., L.R.C.P. Lond., D.P.H., R.C.S.I., has been appointed Medical Officer to the No. 5 District Market Harborough Union, Medical Officer of Health Market Harborough Rural Sanitary District, and Medical Officer of Health to the Oxenden Rural Sanitary District, vice Thomas Macaulay, resigned.

RHIND, THOMAS, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the No. 1 Western District, Billesdon Union, vice E. V. Phillips, resigned.

SALT, A. H. D., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Fourth Sanitary District of the Blean Union, vice Wheeler, resigned.

SELBY, EDMOND WALLACE, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Doncaster General Infirmary and Dispensary.

SEWILL, J. SEFTON, M.R.C.S., L.R.C.P., L.D.S., has been appointed Dental Surgeon to the St. Marylebone General Dispensary.

SHILLITOE, ARTHUR, M.B., B.C. Cantab., L.R.C.P. Lond., M.R.C.S., has been appointed Registrar to the Lock Hospital, Paddington.

SYMONDS, CHARTERS T., M.S., M.D Lond., F.R.C.S. Eng., has been appointed Consulting Surgeon to the Stockwell Orphanage, vice Durham, deceased.

TODD, H. B., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health to the Charlton King's District Council.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, London, W.—Assistant House Surgeon. Board and residence provided.

POPLAR HOSPITAL FOR ACCIDENTS, Blackwall, E.—Senior Assistant House Surgeon. Salary £80 per annum, with board and lodging.

SALFORD UNION INFIRMARY, Hope, near, Eccles.—Assistant Medical Officer. Salary £130 per annum, with furnished apartments in the Infirmary. Applications to the Clerk to the Guardians, Union Offices, Eccles New-road, Salford.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Board and residence provided, and an honorarium of £10 given, after six months satisfactory service.

STROUD GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging and washing.

UNIVERSITY OF GLASGOW.—Two Examiners in Medicine.

YORK DISPENSARY.—Resident Obstetric House Surgeon to attend midwifery cases at their own homes, unmarried. Salary £150 per year, with furnished apartments, coals and gas.

Births, Marriages, and Deaths.

BIRTHS.

FRAZER.—On July 2nd, at Upton Lodge, Devonshire-place, Eastbourne, the wife of Kenneth Frazer, B.A., M.D. Dubl., of a son.

HOWARD.—On July 1st, at Wealdstone, Harrow, the wife of Arthur Walters Howard, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

MARRIAGES.

WATKINS—ASTEY.—On July 6th, at St. Mary Magdalen, St. Leonards-on-Sea, C. Stuart Watkins, M.R.C.S. Eng., of Warrior-square, to Henrietta Elizabeth Astey, of St. Leonards-on-Sea.

WHEELER—ARUNDEL.—On the 5th inst., at St. Mary's, Stoke Newington, by the Rev. Richard Holmes, B.A., Charles B. Wheeler, M.D., eldest son of Henry Wheeler, M.R.C.S., L.R.C.P., to Ethel, eldest daughter of the late Samuel Drew Arundel, of Stamford-hill, N. (No cards.)

DEATHS.

CASSIDY.—On June 14th, at Purnea, Bengal, Cecil Valois Clemons, son of Surgeon-Captain and Mrs. C. Clemons Cassidy, aged four months and ten days.

HARRISON-CAPES.—On June 25th, suddenly, at Poitiers, on his return to England, George Augustus Harrison-Capes, M.R.C.S., of Sible Hedingham, Essex, and Rue du Lycé, Pau, aged 82 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to the Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the half-year ending June, which was given in the number of the 29th ult., completed the first volume of the year 1895. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1895 are now ready. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s*.

To be obtained on application to the Manager, accompanied by remittance.

THE LANCET AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

MEDICAL ADVERTISING.

THE following card cannot be commended in any sense. "Dr." Gill appears in the Medical Register as having the Licence of the Apothecaries' Society and as having received it in 1894. We trust that he will reconsider his titles and his methods.

> Dr. Gill's Surgery, 28, Stainsby-road (corner of Hind-street), Poplar, E. Hours: Before 12; after 6. Fees: Consultation and Medicine, 6*d*.; Visit and Medicine, 1*s*.; Midwifery, from 15*s*.; Vaccination, 1*s*. For many years Assistant to the late Dr. Sharp, of Guildford Road and Burdett Road.

Kasak.—It is not possible for us to give definite replies to our correspondent's queries. We recommend him to be cautious in what he says. Possibly his remarks would be held to be privileged, but this is a debatable question.

Medico-Chirurgico (London) has not complied with the regulations in regard to his name and address.

THE SKOPTZY.

THERE is, it seems, a very singular religious sect in Russia, whose chief tenet consists in castration. These ridiculous fanatics are said to be convinced that mankind can only obtain admission to Paradise in a mutilated condition, and consequently all males who join their ranks must submit to be deprived of their testicles, but whether the females have to undergo spaying or any analogous operation is not clear. According to M. E. Teinturier, who has written a book entitled "Les Skoptzy," these blind enthusiasts are tolerably numerous; but, happily, there is one good point connected with their particular form of madness—it cannot be transmitted hereditarily.

Carpenter.—The authority for tolling a church bell is to be found at the end of one of the prefaces to the Book of Common Prayer, headed "Concerning the Service of the Church." The direction applies to morning and evening prayer only. The Prayer Book is scheduled to an Act of Parliament, and is therefore of statutable authority. There is no direction whatever for the tolling or ringing of a bell previously to the celebration of the Holy Communion, and any such ringing stands, therefore, in just the same position as the ringing of a bell by any person for any purpose—neither more nor less.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—Dr. Donovan surely flatters himself when he says, in your last issue, that an L.S.A. has no more right to call himself "Dr." than a curate has to call himself Archbishop of Canterbury, as he thereby implies that there is as great a difference between an L.S.A. and an M.D. as there is between a curate and the Archbishop of Canterbury. When Dr. Donovan says that "the licence of the Society of Apothecaries gives its holder a kind of legal right to act as a general practitioner he is probably unaware that it is the same kind of right, neither more nor less, that an M.D. has, as an L.S.A. qualified since 1887 is qualified in medicine, surgery, and midwifery. I am sure many will agree with me that the degree or qualification a man holds is alone no criterion either to his professional abilities or his moral qualities. I myself have known several M.D.'s who display the grossest ignorance of their profession, and I also know several M.D.'s who resort to means to obtain patients which show a complete absence of all sense of honour or gentlemanly feeling. Of course, there are good and bad with all degrees and qualifications, but surely it would be more fair to judge a man by his actions and apparent abilities than by the letters he has after his name. As to title, it is my humble opinion that it is simply a matter of taste; it makes very little difference what a man has on his door-plate, as some most successful general practitioners have simply "Mr. So-and-so" It has struck me that several letters under the above title were written by men who have either been disappointed or are suffering from dyspepsia, and who would have been better employed doing something to prove their own superiority than crying in vain to prove the inferiority of men who are perhaps at least their equals, but do not happen to possess the same qualifications as themselves. I am, Sirs, yours faithfully,

July 9th, 1895. L.S.A. Lond.

To the Editors of THE LANCET.

SIRS,—May I venture to ask space in your columns to reply to "M.D.'s" statement in THE LANCET of last week with reference to the new L.S.A. (Lond.)? First, "M.D." states that an L.S.A. is an apothecary, and that only. Now, I question very much whether "M.D." understands the meaning of apothecary, otherwise he could not have made so untrue a statement, as the apothecary is almost, if not completely, one of the past, as "M.D." applies the designation. To the second part of this statement I say an L.S.A. is a surgeon and entitled to style himself so. Secondly, I would remind "M.D." that the Society of Apothecaries are apothecaries in name, and name only, having the power to grant a licence in medicine, surgery, and midwifery—a triple qualification; and I ask "M.D." what body whose examination is a pass examination only has more power than to grant licences? Further, I would remind "M.D." that the persons who examine and thus grant the diploma of the Society of Apothecaries are not men who only hold a sort of legal right to practise medicine, but some of the leading and best surgeons and physicians in London. Thirdly, "M.D." states that the L.S.A. only holds a sort of legal right to practise medicine. Pray what more legal right, or any other right, has "M.D." to practise than the L.S.A.? Fourthly, "M.D." thinks the Society of Apothecaries should be done away with, as it is not wanted. I ask him, Are all the universities that grant a degree in medicine wanted? I think a few of the many universities in Great Britain that give degrees in medicine might with advantage be deprived of this power, and then perhaps the status of "M.D." would be higher than at the present time.

I am, Sirs, yours faithfully,

July 8th, 1895. A NEW L.S.A.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to protest against the manner in which Dr. Donovan speaks of the L.S.A. London. When he says "it is quite time that the Society ceased to grant its licence" I take it that he considers the diploma too easily obtained, and that its holders are "inferior articles." To-day the Final L.S.A. is quite equal to, if not better than, that of the Edinburgh College. True the holder of the latter diploma can affix almost half the alphabet to his name, whereas the former only gets L.S.A., but I think the L.S.A.'s chance of getting an appointment is no less than his Scotch brother's. Had an M.D. of a *good* university or even a conjoint (London) man wished for the abolition of the L.S.A., I could have bowed my head and remained silent, but under the circumstances I cannot, and am not ashamed to sign myself—Yours faithfully,

July 10th, 1895. L.S.A. LOND.

To the Editors of THE LANCET.

SIRS,—May I be allowed to protest against the tone of Dr. Donovan's letter in your last issue, which seems to me to be lacking in courtesy towards a large body of his fellow practitioners? When he states that the L.S.A. has "a kind of a right to act as a general practitioner" the sentence would have been more correct, as well as being in better taste, with the word "kind" omitted. He also seems to be under a misapprehension when he says that the Pharmaceutical Society has supplied the place of Apothecaries' Hall. Perhaps he is not aware that the L.S.A. is now a qualification that compares favourably with those granted by many other licensing bodies, and is not merely a licence for the compounding of drugs. The L.S.A. has as much, and no more, right than any other diplomate to the courtesy prefix of "Dr."

I remain, Sirs, yours faithfully,

July 8th, 1895. M.R.C.S., L.R.C.P., L.S.A.

To the Editors of THE LANCET.

SIRS,—Kindly allow me to say that there is no such statement in my letter as that which Dr. Keser imputes to me. I have not stated that the State examination in Germany confers any title. As Dr. Keser possesses Swiss diplomas I assume that he is Swiss. I have travelled a good deal in Switzerland, but have felt no temptation to draw medical models from that country. I can only attribute Dr. Keser's misstatement to an imperfect knowledge of our language. To this same cause may also be attributable his strong language on the State examination in his country, which can only reflect upon its M.D.'s who are prohibited from practising till they have passed this test of professional competency. I am, Sirs, your obedient servant,

July 9th, 1895. M. H. FEENY.

To the Editors of THE LANCET.

SIRS,—I confess that I am quite taken aback by the vigorous protests aroused by my statement concerning the L.S.A. and the title. I have so often heard the assertion made without contradiction—not only by men holding the diploma in question, but by others, who have referred to it as a great grievance—that I believed it to be a fact well known and unquestioned. Obviously, however, I must either substantiate my words or withdraw and apologise for them; and if you and my challengers will allow me until next week, or even the week after next, I promise that I will do one or the other.

I am, Sirs, yours obediently,

July 9th, 1895. NOT L.S.A.

EMBALMING.

WE have received from Mr. Halford Mills, of Cambridge-place, a pamphlet in which he directs attention to the advantage in some cases of preserving the dead body by the American method of embalming. For the purpose of conveying bodies of the dead to distant places embalming has been largely resorted to in the United States, and as there practised it is shorn of the repulsive features usually associated with this process. The system consists in the withdrawal of the decomposing gases and fluids and the thorough washing out of the circulatory system with an antiseptic and preserving fluid. In most cases a small opening in the arm is all that is necessary to accomplish this; and after the operation the corpse has an appearance which renders unnecessary any after "touching up," and the substance of the structure is preserved, as well as the lineaments of the countenance and complexion. As the fluids are extracted from the body, the corpse may be deposited in a wicker coffin without any of the unpleasant results which usually attend the use of such coffins.

Inquirer.—Applications for the appointment of prison surgeon should be made to the Prison Commissioners at the Home Office, Whitehall, S.W. (Secretary: Col. M. Clare Garsia), for English appointments, and candidates are selected on their merits. Surgeons in Scotch and Irish prisons are appointed by the same department, but under separate regulations.

LYSIDINE.

To the Editors of THE LANCET.

SIRS,—Can any of your readers give me some information as to the action of the new remedy "lysidine" in gouty affections? Does it produce any disturbing symptoms, and is its effect permanent or merely temporary? I am, Sirs, yours faithfully,

July 4th, 1895. A SUBSCRIBER.

Mr. T. C. Hubbard.—It would be difficult to take any action before identifying the medical men who are responsible. If there is any clue to them their names and their bills should be forwarded to the respective bodies whence they derive their qualifications.

M.P.S.I.—The board of guardians, who are on the spot and conversant with the details, ought to see that our correspondent is not wronged in the way that he considers himself to be.

PENALTIES ON MEDICAL PRACTITIONERS.

THE following amusing passage from *Health News* will show that even though the medical practitioner's life, like the burglar's, may not be an invariably happy one, yet times have changed for the better:—

> There was a time when physicians were bound to a strict attention to the welfare of their patients by something besides the consideration of their own credit and profit, for at Dijon, in 1386, a physician was fined by the chief magistrate fifty golden franks (as well as being imprisoned for a time) for not having completed the cures of some persons whose recovery he had guaranteed. And the beautiful Austrigilda, Consort of Gontran, King of Burgundy, was in the sixth century permitted by her husband, in compliance with her dying request, to have her two physicians slain and buried at the same time as herself. St. Foix, who chronicled this fact, omitted to mention whether this cruel deed occurred by way of punishment for their ill-success or out of her attachment to them. It has been suggested that this arrangement had the advantage of relieving the king from any indebtedness to those ill-used and ill-requited doctors, possibly a consideration which had some weight with the too indulgent Royal husband in inducing him to accede to his consort's singular request.

A Practitioner at Blackpool.—Judging by the facts as set out by our correspondent, we cannot but regret that such medical men as desire to do so should not be allowed to continue attendance on their patients when these are removed to the Blackpool infectious hospital. As a rule, the most advantageous plan is to favour such attendance, provided it is carried out at the cost of the patient and subject to the rules as to general control laid down by the local authority under the advice of their medical officer. Such a plan has often been found to do more than anything else to secure the admission of better-class patients, such as those in tradesmen's houses, who, by reason of their occupation, constitute a risk of infection to the public. But we are bound to admit that in some large hospitals this scheme is not found to work well, and hence the ordinary medical practitioner only visits cases in consultation with the hospital medical attendant. The circumstances of each individual town and district must settle which is the best line to be taken, and local opinion can generally best decide which method will tend to make the hospital most attractive to the public and most useful in preventing the spread of infection. In some towns medical men are by no means unwilling to get rid of attendance on the bulk of their infectious cases, especially if this can be done without the risk of the patients being handed over to a competing medical practitioner. We do not doubt but that a general expression of opinion, one way or the other, by the medical men practising in Blackpool would receive every consideration at the hands of the town council.

Perseverance.—The title is one of courtesy only. Our correspondent must judge for himself how far it should be adopted. The scale of fees must be dictated by the circumstances of the patients.

PROFESSIONAL RISKS.

To the Editors of THE LANCET.

SIRS,—In Max Nordau's "Degeneration" (Heinemann's edition) occurs the following capital rendering of a passage which should afford food for thought in many particulars to busy practitioners of the healing art. It may well be left to produce its effect unaided:—

"In an exceedingly amusing French farce, *Le Homard*, a husband suddenly returning home one evening surprises a stranger with his wife. The latter does not lose her presence of mind, and says to the husband that, having suddenly been seized with illness she had sent her maid for the first available doctor, and that this gentleman was the doctor. The husband thanks the gallant for his speedy appearance, and asks if he has already prescribed anything. The gallant, who, of course, is not a doctor, tries to make himself scarce; but the anxious husband insists on having a prescription, so that the Galen, bathed in cold perspiration, is compelled to give one. The husband casts a glance at it; it consists of wholly illegible marks. 'And will the chemist be able to read that?' asks the husband, shaking his head. 'As if it were print,' asseverates the false physician, again trying to make his escape. The husband, however, adjures him to remain, and holds him fast till the maid returns from the chemist. In a few minutes she makes her appearance. The Galen prepares himself for a catastrophe. No. The maid brings a phial of medicine, a box of pills, and some powders. 'Did the chemist give you those?' demands the Galen in bewilderment. 'Certainly.' 'On my prescription?' 'Of course it was on your prescription,' replies the astonished maid. 'Has the chemist made some mistake?' interposes the troubled husband. 'No, no,' our Galen hastens to reply; but he contemplates the medicines for a long time and becomes lost in reverie." (*Vide* page 394)

I am, Sirs, yours faithfully,

July 8th, 1895. PLACEBO.

"LIQUEUR ADVOCAAT."

IN regard to our analytical notice of this preparation last week, Messrs. Simundt, Slater, and Co. write that they are not, as stated, the original manufacturers, but the agents of the original manufacturers, Messrs. Kruijmel and de Wit of Arnehem, Holland.

MEDICAL ADVERTISING AT SOUTHPORT.

To judge from the *Southport Visiter* Southport seems a collection of hydropathic institutions, supported by advertisements in which the medical officers figure in a way that cannot be approved. The advertisements are jumbled together with that of a remedy for "restoring regularity in married women."

PRACTICE IN NEW ZEALAND.

To the Editors of THE LANCET.

SIRS,—Can any of your readers give me any information concerning medical practice in New Zealand? I am, Sirs, yours truly,

July 3rd, 1895. M.B. & C.M.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Gt. Northern Central (2.30 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Gowers.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 to 6 P.M. Dr. Morgan Dockrell: Syphilis.

SATURDAY.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—5 to 6 P.M. Dr. Morgan Dockrell: Lichen Planus.

During the week marked copies of the following newspapers have been received:—*Glasgow Herald, Sheffield Independent, Birmingham Post, Carlisle Express, Science Gossip, Irish Daily Independent, Scotsman, Times of India, Brighton Gazette, Builder, Liverpool Daily Post, Architect, Pioneer Mail, Yorkshire Post, North Star, City Press, Leeds Mercury, Wisbech Standard, Morning, Bristol Mercury, Midland Counties Express, Sanitary Record, Hertfordshire Express, Family Doctor, Provincial Medical Journal, Princess, Manchester Courier, Bristol Times, Nature, East-end News, Courrier de la Presse, Local Government Chronicle, Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, Mining Journal, Reading Mercury, The Gas World, Surrey Advertiser, Cape Times, Weekly Herald and North Middlesex Advertiser, North Wales Chronicle, Milom News, Southport Visitor, East London Observer, Guy's Hospital Gazette, Local Government Journal, Derby Mercury, Alliance News, Putney News, Midland Times, Rugby Advertiser, Kelso Mail, Preston Herald, Hawaiian Gazette, Umpire, Thanet Guardian, Sandgate Telegraph, North Queensland Herald, Tenby Observer, South Australian Register, Cambridge Express, Brisbane Courier, &c., &c.*

Amyloid Indigestion,

ITS PREVALENCE AND TREATMENT.

A MOST interesting and instructive paper was read by Dr. J. H. Kellogg at the meeting of the American Medical Association this year. Under the title "New Methods of Precision in the Investigation of Functional Disorders of Digestion," he proceeded to lay before the Congress the results of his observations of no less than 4000 cases of Dyspepsia.

This searching investigation of the whole subject led him to the surprising conclusion that the failure to digest starch is one of the most common forms of dyspepsia, and he produced convincing statistical proof of his contention.

This seems to throw a new light upon the great difficulty that many practitioners find in dealing with the many forms of indigestion. It is a matter of common knowledge and regret that such cases are among the most persistent with which the physician has to deal, and it would perhaps be as well therefore to see how far the researches of Dr. Kellogg will help to solve one of the most difficult problems of modern medicine. If, as we can but believe from the results of his painstaking investigations, amyloid indigestion is so very common, it would seem that the part played by the saliva in the digestive process has been very much underestimated.

The reason for this is not far to seek. It is generally believed that ptyalin, the active enzyme of the salivary secretion, will not produce amylolysis in any but neutral or alkaline media. This opinion appears to be not altogether well founded in the light of the latest research. For instance, in criticising Dr. Kellogg's paper, Dr. Webster of Chicago stated that it is not generally known that salivary digestion may continue in the stomach for from thirty to sixty minutes after ingestion of food. Chittenden and Griswold even go so far as to say that a small proportion of acid promotes the activity of the salivary ferment. Dr. Arthur Gamgee, in his exhaustive work "Physiological Chemistry of the Animal Body" (Macmillan, 1893), summarises past and present investigation by saying—

"We may safely conclude that in the first stage of gastric digestion—i.e., for a period up to about half an hour—the conversion of boiled starch into dextrin and maltose doubtless proceeds actively, but that it then ceases, under the influence of acid proteid and free acid."

If then, the symptoms point to amyloid rather than albuminoid indigestion—and according to Dr. Kellogg's statistics the former is far more common than the latter—it would seem to be necessary to apply a digestive agent directly after a meal, so that complete amylolysis can take place before the gastric juice becomes sufficiently acidified to stop the process. As the cause of the disease is either a deficiency in the supply of saliva, or of enzymic potency in the saliva, it is evident that the administration of routine stomachic sedatives and stimulants will be valueless in this variety of indigestion. It is not the stomach but the salivary gland that is at fault.

A fresh difficulty arises if stimulation of the salivary glands is attempted by means of acids, because the increased quantity of acid in the stomach will neutralise the increased quantity of ptyalin. The only course open is to find some substance which will do the work of the deficient ptyalin and thus imitate as closely as possible the normal digestive process. In beating about for an artificial enzyme to replace the natural one, malt-diastase occurs to the mind at once. This substance, called from its marked amylolytic powers, vegetable ptyalin, is closely allied to animal ptyalin in chemical composition, and acts powerfully on starch, converting it into maltose. The ultimate product of the digestive process by means of this enzyme is chemically identical with that produced by animal ptyalin, and like the latter it acts in alkaline, neutral, or feebly acid media.

The very best form in which to administer vegetable diastase is undoubtedly as malt extract, but it is necessary to select a good extract because many of the malt extracts of commerce are woefully deficient in diastase. In deciding between the clamorous claims of various processes it is well to be guided by those eminent authorities who have thoroughly sifted the subject, and are therefore qualified to judge. The concensus of medical opinion is unquestionably in favour of the Kepler Extract of Malt as the purest, best, and richest in diastase.

As THE LANCET appreciatively says:—

"The Kepler is the best known, and in this country the largest used, Extract of Malt. It is as distinct an advance in therapeutics as was the introduction of cod-liver oil. It is one of the best remedies for atonic dyspepsia, and is undoubtedly useful in consumption and other wasting diseases."

The BRITISH MEDICAL JOURNAL recognises the perfection of our process and product:—

"We can recommend the Kepler Malt Extract. Being prepared at a very low temperature, its qualities are not deteriorated nor is its flavour spoiled. It is very favourably spoken of by physicians both in respect to its nutritive and digestive properties and as being of very agreeable flavour."

The MEDICAL RECORD expresses its opinion with no uncertain voice:—

"Kepler Extract of Malt is undoubtedly the best, the richest in diastase, and the most largely used. We have witnessed the process of manufacture, have tested it, and are satisfied that it is not only unsurpassed, but unequalled. It is the Extract of Malt which every physician prescribes."

The MEDICAL PRESS AND CIRCULAR says:—

"Very delicious to the taste, and has been found by analysis to be exceedingly rich in diastase."

The MEDICAL TIMES AND GAZETTE awards us the topmost place:—

"By far the best. The one most widely known and most largely used in this country."

The official text of the award conferred upon the Kepler Extract of Malt at the recent Chicago Exposition appropriately rounds off the list:—

"For high starch-converting or diastastic power, combined with excellent flavour and odour."

3000 Test 5 times B.P.

ARMOUR'S STANDARD PEPSIN.

Armour & Co. guarantee their Standard Pepsin to answer the new U.S.P. test, and to be 5 times the strength of Pepsin B.P.

CAUTION.—This guarantee of strength only applies to original bottles (1-oz., 4-oz., 8-oz., and 1-lb.), bearing the regular Armour Label—and the Shield Trade mark as here shown.

POWDERED PEPSIN, SCALE PEPSIN, OR GRANULAR PEPSIN.

TESTING SAMPLES FREE.

CLINICAL DIETETICS.

Pre-Digested Foods

are now, more than ever, relied upon by Physicians in the treatment of disease.

ARMOUR'S PEPTONISING TABLETS, free from the slightest taint of toxic principles, are put up in tubes containing 15 tablets, accompanied by convenient recipes for pre-digesting milk and other foods.

SAMPLES SENT FREE.

ARMOUR & CO.,
59, Tooley Street,
London, S.E.

ARMOUR & CO.

TRADE MARK.

London Office:
59, Tooley St., S.E.

ARMOUR'S GLYCEROLE PEPSIN.

A clear, concentrated Solution of Armour's pure 3000 test Pepsin. Combines elegance, ease in dispensing, and economy, with real therapeutic value. Each ten minims will digest 3000 grains of egg albumen in six hours, and is guaranteed to be equal to 5 grains Pepsin B.P.

For suggested combinations with Bismuth, Iron, Strychnine, Quinine, Podophyllin, Iridin, Euonymin, &c., see ARMOUR'S Formulary, sent post free on application.

GLYCEROLE PANCREATIN.

A similar Solution of Pancreatin and of equal strength.

For internal administration and pre-digesting foods.

IT IS NEVER CALLED A LIEBIG.

ARMOUR'S EXTRACT OF BEEF.

(SOLID.)

Perfectly pure concentrated Beef, retaining all its stimulating and peptogenic properties without burnt taste, added salt, or chemical preservatives.

ARMOUR'S VIGORAL

(LIQUID EXTRACT).

With added nutritious constituents.

A REAL BEEF FOOD.

The Baillie Lectures

ON

THE CARDIO-VASCULAR CHANGES OF RENAL DISEASE, WITH SOME OBSERVATIONS ON THE LARGER ARTERIES.

Delivered at St. George's Hospital on June 19th and 26th and July 3rd, 1895,

BY W. HOWSHIP DICKINSON, M.D., F.R.C.P. LOND.,

HON. FELLOW OF CAIUS COLLEGE, CAMBRIDGE; CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE I.

Delivered on June 19th, 1895.

GENTLEMEN,—Excepting what has to do with bacteria it may be said that no observations in pathology have been so fruitful in results as the great discovery of Bright. I do not now propose to deal with this as regards the kidneys themselves, but only to touch upon some of the systemic consequences of renal disease which Bright partly, I may say in large part, made known. Bright noticed the hypertrophy of the left ventricle, and attributed the muscular increase to abnormal resistance. He inferred that there was an obstacle in the outward course of the blood, and assigned the capillaries as its probable situation. The immediate cause he considered to be in the impurity of the blood, which in some way interfered with its transit through these channels, which expose to the blood so large a surface and maintain with it such intimate relations. This theory held its ground without modification or question until Dr. (now Sir George) Johnson observed the thickening of the muscular coat of the arterioles, and was led to the belief that the hindrance was not in the capillaries, as Bright had supposed, but in the minute arteries thus thickened. Johnson argued that the capillaries were not muscular, and therefore not contractile, while the arterioles were both. In this view the arterioles became hypertrophied in their efforts to keep the impure blood out of the tissues; the heart became hypertrophied in its endeavours to overcome the resistance thus occasioned. The muscularity of the arterioles is not to be disputed, and it is known to physiologists that under certain influences, connected particularly with the nervous system, these vessels have the power of contracting, and so cutting off the blood from the tissues; but whether this stopcock action, as Johnson called it, is the essential factor in the cardio-vascular change of heart disease remains to be seen. The capillaries have been shown to be contractile, though not muscular, and the observations of Johnson do not disprove the theory of Bright.

Leaving this contest as yet undecided, I must note the appearance of another combatant, or rather hostile alliance, upon the field. Sir W. Gull and Dr. Sutton, neither of whom, I grieve to say, are with us now, came down in force upon the position of Johnson, and a great battle ensued, which was waged with obstinacy and even with asperity. The allies disputed the muscular thickening of the arterioles, and maintained that the only thickening was of the fibrous tissue. Johnson, in upholding the muscular increase, denied the fibrous, the appearance of which he held to be delusive and the result of reagents. The contest was the more obstinate because there was right on both sides, and the more embittered because on both sides there was wrong. Without staying to recall the fortunes of the fight, I may say that I took then, and have taken since, some pains to satisfy myself of the actual condition of the arterioles, and will briefly repeat, what I said at an early stage of this controversy, that the muscular thickening as described by Johnson is a fact which does not admit of doubt. On the other hand, it is equally certain that with this there is fibroid overgrowth, however brought about. The champions of fibrosis did not attribute the vascular change to the renal or acknowledge any steps in the pathological process, but they regarded both as the parallel and simultaneous results of a baneful tendency which pervaded the whole body like original sin, affected at the same time the vessels and the viscera, and produced a general deterioration, which they likened to the effects of age. This comprehensive theory is probably not entirely without foundation; there *is* such a thing as general fibrosis, particularly as a form of senile decay, and of this general fibrosis the granular kidney may sometimes be a part. But it is abundantly clear that this explanation suffices but for a small minority of the cases in which cardio-vascular changes are associated with renal. By far the greater number begin with disease local to the kidney, and proceed from step to step through the blood to the vessels and the heart. Inflammation limited to the kidney, produced by cold or scarlet fever, perhaps in a child where there can be no question of general fibrosis, except as a result of renal disease, is constantly and rapidly followed by the special cardio-vascular hypertrophy, and that in its most extreme and characteristic shape. That the granular kidney is essentially a local matter and not a mere subdivision of a general fibrosis, as Gull and Sutton tried to make us believe, is borne out by what happens to the liver. Of all the organs in the body the kidney and the liver are the most liable to fibrotic change. If the kidney is affected thus merely as part of a general change the liver surely ought to participate. But it does not do so. I found that in 250 cases of granular degeneration of the kidney, the liver displayed the corresponding change—that is, cirrhosis—in only 37 instances, a proportion of 1 in 7.[1] Granulation of the kidney and cirrhosis of the liver do not go together, as they should do if the fibrotic change in each were due to a common cause. The fact is that, putting aside the general effects of valvular disease of the heart, the liver and kidney are each influenced by causes proper to themselves, not common to the whole body. The liver is made fibrotic chiefly by alcohol, the kidney chiefly by climate, lead, gout, heredity, and as the sequel of acute nephritis. It has always seemed to me that the morbid independence of these organs is a strong if not a conclusive argument against the theory of general fibrosis as propounded by Gull and Sutton. On every ground, therefore, we must accept that as a *general rule*—I do not say there are no exceptions, but I am sure they are few—the renal change is the initial mischief, the *fons et origo* of which the cardio-vascular changes are the results.

The only question that presents itself as admitting of doubt is by what process the renal change brings about the cardio-vascular. The impurity of the blood due to the imperfect action of the kidneys may be accepted as an intermediary, but how does it produce the effects in question? There is presumably an obstruction which gives rise to increased blood pressure, and this to hypertrophy of both muscle and fibre. But where is the obstruction? Is it in the capillaries, as Bright supposed, or are we to place it with Johnson in the arterioles? It seems unlikely at first sight that the heart and the arteries should become hypertrophied by acting against each other—it looks like a want of the common consent which we usually find in nature; but how shall I say it is not so? There are many things which are too wonderful for us, four of which have been mentioned by a royal and inspired author. The action of the heart and vessels may be, like these, beyond our comprehension; but it is not beyond our inquiry. I have ever found, when a difficulty presented itself, that the best way was not to argue or even to reflect, but to seek for additional facts. Being able to get them is the great advantage we have over our brethren the theologians. The facts at their command cannot be added to by observation, whatever talent may be expended in reconsidering the stock in hand. With us the main endeavour is to collect fresh particulars, and nothing further is necessary than to let them speak for themselves. Unlike the students of theology, we are able to push our inquiries beyond death, and take for our motto, "Nec silet mors."

As possibly throwing light upon the rival theories of obstruction in the capillaries and in the arterioles, I thought it worth while to look more widely than had hitherto been done at the distribution of the arterial hypertrophy. If this should prove to be limited to the smaller vessels, which alone can be credited with the stopcock action, then the stopcock or inhibitive action may be the cause of the hypertrophy, or of as much of it as concerns the muscular coat; if, on the other hand, the large arteries should be found to partake of the same alteration, then we must look for some cause which acts alike on large and small. With this view I have examined a series of arteries, including some of the largest: the aorta, the innominate, the common femoral, and the renal. Sections of these vessels made carefully in the same respective

[1] Albuminuria, second edition, p. 171.

Digitized by Google

situations were placed under the microscope and outlined on paper with the camera lucida and a uniform magnifying power of 6·35 diameters. The tracings thus obtained were then measured both as to the thickness of the wall and the circumference of the vessel. The number of vessels thus treated amounted to 139, which were supplied by forty-nine individuals mostly chosen as the subjects of marked renal disease or as presenting the type of health. The conclusions are based upon the whole number of vessels of each kind and not derived from selected specimens. As a standard of health I have taken eighteen post mortems, generally after accident or acute disease—ten of males and eight of females. In the male series I have added two cases of acute nephritis, in which, as there was no time for, nor any evidence of, cardio-vascular change, the vessels may be taken as healthy and as furnishing a second standard of comparison. The granular kidney is represented by sixteen male subjects and seven female. In the latter series I have thrown together, as exhibiting virtually the same condition, and that the fibrotic, kidneys described as *granular* and as *white contracting*. The male series shows that with the granular kidney the aorta is thicker than in health as 42 to 39, and thicker than with acute nephritis as 42 to 31. The innominate with the granular kidney gives a thickness of 0·41 in., that with health 0·35 in., and that of acute nephritis 0·30 in. The common femoral gives with the granular kidney a thickness of 0·33 in., with health that of 0·26 in., and with acute nephritis that of 0·24 in. The renal gives with the granular kidney a thickness of 0·25 in. in health, and with acute nephritis one of 0·18 in. Both coats are thickened, as will be seen on reference to the accompanying table. The muscular shows the change with more exactness than the fibroid, for it is not exposed in removal, or liable, as the outer coat is, to have any part left behind. The circumference of the vessels of each kind is also increased with the granular condition, that of the aorta giving 13¾ in., as compared with 11¼ in. in health and 10¾ in with acute nephritis. The innominate, femoral, and renal showed similar increase under the same circumstances, as is displayed in the table. The comparison, as far as relates to the female sex, will be seen to give similiar evidence. The aorta, the innominate, and the femoral are all increased under the renal change in question in the total thickness of the wall, in the thickness of the muscular coat, and in circumference The only exception is in the case of the renal artery in the female, which presents an increase of circumference, but none in the thickness of the wall; only eight specimens, however, of this vessel in this sex were examined, and the number is too small to give weight to the exception.

I have added as collateral illustrations two instances which show the absence of arterial thickening, as of cardiac hypertrophy, with the large white and the lardaceous kidney; and a third which presents a large amount of aortic thickening in connexion with atheroma without renal disease. This aorta, which displayed a large endoarterial deposit, gave a total thickness of 0·57 in., which was greater than those in any of the renal cases, the thickest aorta with renal disease measuring 0·55 in. With the aorta thus thickened by atheroma the change did not extend to the innominate, which was thinner than the average of health.[2] The above measurements will, of course, be understood to apply not to the actual dimensions of the vessels but to those of the representations uniformly magnified as stated.

It has been well known since the observation of Sir G. Johnson—which represents a great truth, however it is to be interpreted—that with the chronic granular kidney the arterioles, even to the smallest, become hypertrophied. For the purpose of this inquiry I thought it would be of interest to ascertain as far as practicable how the degree and kind of thickening here compared with that of the larger vessels. To this end I have examined afresh a number of minute arteries belonging to the pia mater and median fissure of the brain, which are in my possession as the results of former work. Some have been preserved in Canada balsam, others in glycerine. I have dealt with these specimens graphically, making outlines of them with the camera lucida, as in the case of the larger vessels. I may say that I have made no selection—by judicious selection it is possible to prove anything—but I have taken all that came to hand as either typically healthy or connected with typical granular kidneys. The results are before you. The outlines show that under renal disease there is generally, but not universally, thickening of the wall, and that this affects both the muscular and the fibrous coats. The total thickening, and that of each coat, is, judging by the eye, generally greater in the small vessels than in the larger, though demonstrably present in both.

Putting all the facts together, and including what is common knowledge as to the left ventricle, we may formulate the general statement that in connexion with the chronic granular kidney we have hypertrophy of the muscle and of the fibrous tissue belonging to the whole arterial system connected with the left side of the heart, and of the muscle of the heart itself. It is probable that had the inquiry been carried into the pulmonary vessels similar changes might have been found there. We see indications of them in the hypertrophy of the right ventricle, which in these circumstances is almost invariably associated with that of the left, though on a smaller scale. Looking at the import of the changes which have been recorded, we recognise, first, the general application of the ancient dictum that muscle becomes hypertrophied when resistance is opposed to its contraction. We next see the influence of another law, which may act together with, or independently of, the first—namely, that tissues, whether epithelial, fibrous, or muscular, become over-nourished and overgrown as the result of habitual congestion or over-pressure, or undue retention, of blood within them. As

[2] I may introduce a word as to the methods employed. Sections of the arteries were cut with the microtome and mounted on slides for the microscope. These were reflected on paper with the camera lucida and carefully outlined, all with exactly the same microscopic and optical arrangements. With the magnifying power used the vessels were presented as large enough to be accurately measured. The thickness of the wall was ascertained with a rule graduated to hundredths of an inch. The circumference, taken along the outer edge of the muscular coat, was measured with a rotating instrument such as is used for estimating distances on maps. This gave the circumference in inches and fractions of an inch. The enlarged figures to which I have referred were displayed in the course of the lectures. I believe the measurements may be accepted as accurate.

regards renal disease, it is impossible to separate the question of obstruction ahead from that of over-pressure by their contents upon the arterial walls. Some of the forms of renal disease are attended from their outset with increased blood pressure, others are not. When the pressure is increased, then, sooner or later, there is hypertrophy; when it is not increased there is none. This state of pressure or tension precedes the hypertrophy, for it is evident to the finger, the sphygmograph, and the stethoscope long before there has been time for any structural change. The granulating kidney and the lardaceous may be instructively contrasted. The granulating kidney — beginning, say, in nephritis—is attended from the very first with increased tension and followed as surely by hypertrophy. The lardaceous condition begins with no increase of tension or even with a lack of it; the heart remains small to the last, or, at least, until other renal changes are superadded. It is clear that there is a necessary connexion between the over-tension and the hypertrophy; and as the cause precedes the effect, it must be supposed either that the tension causes the hypertrophy or else that both are the results of some common cause. Searching for the immediate cause of the increase of tension and the hypertrophy which follows upon it, we can only attribute one and both to a difficulty in the emptying of the arterial system caused by an obstruction at or near its outlet, due to the morbid condition of the blood. So far all seems clear. The increased retention of blood within the arterial system is an adequate cause for vascular and cardiac thickening, on the principle which has been already adverted to, by which congestion causes hypertrophy. This would seem to be the essential and simple cause of the fibroid thickening. With regard to the muscular there are other considerations. The arteries are alternately filled by the ventricle and emptied by their own contractility. Peripheral resistance will oppose their contraction and thus occasion muscular hypertrophy. With the large arteries this rule seems of obvious application; they are in the same case as the heart and owe their hypertrophy to similar means. With regard to the minute and terminal arteries, other modes of action are to be taken into view. These vessels, which are known under certain circumstances to exert a special contractile power and thus cut off the blood from the capillaries, have been supposed to do this in renal disease and to owe their hypertrophy to their efforts not to accelerate, but to retard the current. I will not argue for this view or against it, but content myself with stating the facts, or what appear to me to be such, which bear upon it. I think it must be allowed that the smaller vessels are generally more thickened than the larger—at least, I have seen some examples of extravagant thickening among the smaller which I have failed to find in the larger vessels.

It often appears that the calibre of the small vessels is lessened in comparison with the thickness of the walls, whereas with the larger there is dilatation as well as parietal thickening. It looks as if the smaller vessels had some special cause of hypertrophy beyond that which affects the larger. There may be a special inhibitory mandate addressed to their muscular tissue, but against this we have to place the fact that the fibrous tissue, to which no such mandate could be held to apply, is at least equally thickened. Whatever be the cause of the hypertrophy, it must relate equally to both coats.

In searching for the primary seat of obstruction, however our attention may be arrested by the arterioles, we must not disregard the capillaries. These have been proved to be contractile, though they are not muscular.[3] These vessels are in more intimate relation to the blood than any others, and may be supposed to be the first to be influenced by its abnormal conditions; and as evidence that they are so influenced we have the appearance of dropsy—or, in other words, of abnormal capillary transudation—at the outset of renal disease. This process is capillary and not arterial, and at least points to a morbid condition of which the capillaries, not the arterioles, are the seat. Arterial obstruction, indeed, must be prohibitive of dropsy by cutting off the blood from the vessels which are its source. These considerations appear to indicate that, whatever be part of the terminal arteries, the capillary system is the point of departure of the series of changes which have been described. Whether these terminal arteries have any special sympathy with the capillaries with which they are so immediately connected is a question which suggests itself. Whatever be the explanation of the vascular changes upon which I have dwelt, it must include the fibrous thickening as well as the muscular.

Without attempting to pursue these questions to the end I will content myself for the present with having demonstrated the fact that under renal disease, putting aside the pulmonary department to which the same rule probably applies, there occurs a hypertrophy of the cardio-arterial system which is universal from its origin to its termination, and comprises not only the ventricle and the arterioles, but affects also the intermediate arteries of every size.

In conclusion, I have to thank Dr. Rolleston, Dr. Lee Dickinson, and Dr. Cyril Ogle for procuring the specimens of which I have made use. My especial thanks are due to Dr. Rolleston—and to a larger extent to Mr. Fenton—for cutting and mounting the sections.

[3] Paper by Dr. Roy and Dr. Graham Brown on "The Blood-pressure and its Variations in the Arterioles, Capillaries, and Smaller Veins." (Journal of Physiology, 1879-80, Part 2, p. 323.)

A Clinical Lecture

ON

CHRONIC INFLAMMATION OF THE UTERUS.

Delivered at the Middlesex Hospital on June 20th, 1895,

BY WILLIAM DUNCAN, M.D., F.R.C.S.,

OBSTETRIC PHYSICIAN TO THE HOSPITAL; SENIOR PHYSICIAN TO THE CHELSEA HOSPITAL FOR WOMEN.

GENTLEMEN,—The subject which I have chosen for this afternoon's lecture is probably the commonest disease to which a woman is liable, and it is not often that one or more of the beds in Prudhoe Ward are not occupied by a patient suffering from chronic inflammation of the uterus. Under the disease just mentioned I include inflammation affecting not only the parenchyma of the uterus (metritis), but also that involving the membrane lining the cervical canal (endocervicitis) and that lining the uterine cavity (endometritis). All the tissues of the uterus are more or less involved in chronic metritis, so that usually endometritis cannot clinically be dissociated from metritis, although in some cases the endometritis is predominant—in others the metritis. The microscopical appearances, thanks to Wyder, Ruge, and others, are now well known, and in briefly mentioning them I will follow the views of Wyder.

When the uterine wall is the chief seat of inflammation we find the whole uterus enlarged—perhaps even to the size of a man's fist—by hypertrophy of the connective tissue with usually some muscular hypertrophy also. The arteries and veins are much thickened by hypertrophy of the tunica adventitia. The connective tissue remains permanently hypertrophied and does not undergo cicatricial contraction. When the membrane lining the uterine cavity is chiefly affected the changes are such that they can be classified under the following heads: (*a*) chronic hæmorrhagic or villous endometritis, (*b*) chronic catarrhal or glandular endometritis, and (*c*) chronic interstitial endometritis.

In the villous or hæmorrhagic form the mucous membrane is greatly hypertrophied, perhaps to four or five times its usual thickness; it is deeper in colour and, instead of being smooth, has become fungoid, and the projections may form true polypi. In some cases there are found small transparent vesicles, which under the microscope are seen to be dilated glands, the openings of which are closed by connective tissue. The inter-glandular tissue is very vascular. In the glandular or catarrhal form the glands are enormously increased in size and become convoluted at their deep extremities; there is also an increase in their number, so that both hypertrophy and hyperplasia coexist, but otherwise the glandular tissue is normal in structure. In the interstitial form a new connective tissue is developed between the glands, and in some parts it converts the latter into cysts; in others of longer duration the glands may have disappeared altogether, so that the mucous membrane is represented by a layer of connective tissue lined by epithelium.

Causation.—It is becoming more and more a well-recognised fact that in the vast majority of cases of chronic inflammation of the uterus the origin is due to bacterial infection. This infection may be, and too often is, gonorrhœal in character,

Digitized by Google

and then not infrequently the inflammation tends to extend beyond the uterus to the Fallopian tubes. A husband may infect his wife directly after marriage if he have the slightest trace of gleet the result of a gonorrhœa which he contracted it may be many years previously and of which he considered himself perfectly cured. Bacterial infection, too, is very common after parturition, especially where any bits of placenta or membranes have been left behind, or where the attendant has examined with a dirty finger or used unclean instruments. Apart from bacterial infection, parturition may be the starting-point of chronic metritis owing to the woman getting up too soon, to the uterus being retroflexed, or to deep lacerations of the cervix, all of which tend to produce subinvolution, congestion, and subsequently inflammation. Again, the disease may be caused by catching cold during menstruation, by the use of a cold injection, which is often had recourse to directly after coitus, and when the pelvic organs are full of blood, in order to prevent conception. Excessive coitus, and especially all operations on the uterus which are not conducted with strict antiseptic precautions, may cause chronic metritis Not a few cases can, I fear, be traced to the careless use of the sound, for it is very easy to carry into the uterus on its point some pus from the vagina.

Symptoms.—With regard to symptoms there are none peculiar to the disease under consideration. The patient usually complains of weakness and a bearing-down pain in the pelvis, which is aggravated by walking or the jolting of a carriage, and which very often shoots into the back and down the thighs; pain over the left ovarian region is three or four times more common than on the right side, and this frequency of left-sided pain is due probably to the left side of the body being weaker and having less resisting power than the right. The "periods" are painful and excessive, lasting perhaps a week instead of three or four days, during which time the patient has to use several diapers daily. This excessive loss is the chief characteristic of villous endometritis, and the periods may be so profuse that a woman sometimes becomes as blanched as is seen in cases of hæmorrhage from fibroids. Clots are often passed, and the pain complained of usually begins just as the period comes on and is relieved in a day or so when the flow is fully established. There is a more or less profuse yellow intermenstrual discharge. Various reflex symptoms not infrequently manifest themselves, such as dyspepsia, a peculiar spasmodic cough, neuralgia of various kinds, and especially often does a woman complain of a severe stabbing pain running round under the left breast. Lastly, hysteria in its various forms may be present, especially in women who are naturally of a neurotic disposition; but it is a grave mistake in these cases to ignore, as some practitioners do, the uterine symptoms and to put them all down to hysteria. A typical instance of this kind I met with only last week, in which a lady aged twenty-five had a miscarriage three years ago. Since then the periods have been excessive and she has suffered from more or less constant severe pelvic pain; during all this time she had taken medicine prescribed by her medical attendant, a very able practitioner, but no local treatment was made. On examining her I found she had an enlarged and very tender uterus, with some erosion round the os uteri and a purulent discharge exuding from it. I communicated with the medical man, and he told me he had diagnosed the enlarged and tender uterus, but as the patient was a neurotic woman he thought general rather than local treatment was indicated. In my opinion the chronic metritis present was the cause of the nerve symptoms and called for prompt local measures.

Physical signs —These are usually the same as those met with in the case just mentioned: a uterus felt on bimanual examination to be enlarged and tender—it may be retroflexed; the cervix is hypertrophied, and instead of being conical it is either cylindrical or bulbous, more or less purplish in colour, and often lacerated; the pain caused on examination is most severe when the uterus is jerked up as in ballottement of the gravid organ. With the speculum the cervix may be seen to be eroded, it may be studded with yellowish vesicles as a result of cystic degeneration, and a yellow discharge may be seen exuding from the os uteri. If the sound be passed it causes pain, sometimes very severe, it enters to an increased distance, three inches and a half or even four inches, and its withdrawal is followed by some blood.

In diagnosing chronic metritis we sometimes have to exclude cancer; but in metritis the discharge is never so offensive or of the peculiar character met with in cancer. When the chief symptom is hæmorrhage we might suspect fibroids or polypi. Now in a case of fibroids the uterus would feel harder and irregular in outline on bimanual examination, whilst perhaps the sound would enter five or six inches. In polypi the symptoms and physical signs—if the polypi be of the small mucous variety—may be precisely the same as in chronic metritis; and it is impossible to distinguish between the two until the cervical canal has been sufficiently dilated to permit of digital exploration. As a matter of fact, in some cases of chronic metritis the mucous membrane assumes, as I have already mentioned, the polypoid form. The treatment for both the diseases is precisely the same. It must not be forgotten that disease of the uterine appendages is a by no means infrequent accompaniment of chronic metritis, and should be carefully searched for, as the complication may modify the treatment, and it certainly renders the prognosis a less hopeful one. Disease of the uterine appendages is in the majority of cases secondary to uterine inflammation, but it may be the primary condition and induce metritis secondarily. Careful examination of the pelvis will always reveal whether the tubes and ovaries be enlarged or not. The rectum should have been previously emptied, and then by the bimanual or, better still, the abdomino-rectal examination—preferably with the patient anæsthetised—we can assure ourselves of the presence or absence of diseased appendages.

Treatment.—We now come to the very important question of treatment. Remembering that most cases of this disease have a bacterial origin, and the starting-point is either a miscarriage or a confinement, the necessity of thoroughly emptying the uterus and of using the most stringent antiseptic precautions in all manipulations on the female generative organs cannot be too strongly insisted upon. Anything that interferes with the proper involution of the uterus—such as the patient getting up too soon after labour—should be avoided. I always give my patients after the third day a mixture containing quinine, strychnine, and ergot, and continue this for three or four weeks. It should be the invariable practice of every medical man to make a vaginal examination about three weeks after delivery in order to ascertain the position of the uterus, so that if, as not seldom happens, it be found displaced backward it can be at once gently replaced and kept in its proper position by a well-fitting Hodge's pessary; this pessary need only be worn for a couple of months, at the end of which time the uterus will have regained its normal size and the flexion have been cured. If, however, the displacement be unsought for and undetected until months later, after the patient has been going about and begins to suffer, then the cure of the displacement is very problematical unless and until the patient again becomes pregnant, and this she is, under the circumstances, much less likely to do; besides which the foundation of chronic metritis may have been laid in the subinvolution which usually results from retroflexion. At all events, the patient may have to wear a pessary for months or years, whereas if the displacement had been detected and rectified early a few weeks would have sufficed for a cure. Backward displacement of the uterus after labour and abortion is by no means infrequent. In a paper read by Dr. Herman before the Obstetrical Society in 1892,[1] he said that in the out-patient practice of the London Hospital he found backward displacement in 19 per cent. of the women who had been delivered or had aborted within the previous three months. According to my experience in private practice the percentage is nearly double this, for of the last 50 cases I have attended, 32 of which were multiparæ and 18 primiparæ, I found within three weeks after labour the uterus displaced back in 18 of the cases, or 36 per cent. This shows the importance of being on the look-out for the displacement after a woman has been delivered.

Other prophylactic measures are—(*a*) care in use of the sound, so that no pus be carried into the uterine cavity; (*b*) that in all operations on the uterus strict antiseptic precautions be used; and (*c*) that the use of cold injections immediately after coitus be stringently prohibited. When chronic inflammation of the uterus is in actual existence the treatment to be adopted will depend on what part of the organ is chiefly affected. In all cases it is advisable to keep the bowels acting well by a morning dose of either Hunyadi Janos, Friederichshall, or Vichy water; tonics, especially preparations of strychnine, are indicated; over-fatigue from

[1] Transactions of the Obstetrical Society, vol. xxxiv., p. 14.

Digitized by Google

too long walks or prolonged standing, as in the case of shop-women, should be avoided. The uterus should be fomented night and morning with a warm douche of at least a quart of water containing two drachms of alum or zinc sulphate. For this purpose a proper douche ought to be used, as the ordinary vaginal injection which a patient gives herself with a Higginson's syringe whilst in a sitting posture is of little use. When the cervical canal is the part affected chiefly we can, after removing the tenacious secretion by means of cotton-wool on a probe, apply some caustic such as pure phenol, iodised phenol, or nitric acid on a cotton-wool probe, or we may introduce a pencil of zinc alum or copper sulphate into the canal and retain it there by a glycerine tampon in the vagina. If the cervix be eroded as well it is a good plan to pass a Ferguson's speculum, then partly fill it with either pyroligneous acid or a 15 per cent. solution of copper sulphate. This is allowed to remain bathing the cervix for four or five minutes, and some of the fluid can be carried into the cervical canal by passing a cotton-wool probe through the fluid. When the cervix is much hypertrophied and congested it has a purplish appearance; in these cases puncturing it in two or three places, and drawing off two, three, or even four ounces of blood gives great relief to the pain and discomfort the patient suffers from. This little operation is only very slightly painful, and can be repeated with advantage several times. There is just one point to be noted—viz., that a small artery may be punctured. If so, the spouting point should be touched with a little liquor ferri perchloridi fortior. Some years ago I punctured the cervix of a lady in my consulting-room one morning, and I was sent for to see her early next day as she had been losing blood all night after using a hot injection the previous evening. I found a little vessel spouting, and at once stopped it with a drop of liquor ferri. The patient expressed herself as greatly relieved from the large loss of blood, and she quickly got well.

When the endometrium is involved, as evidenced by the excessive menstruation and the thin purulent discharge from a tender uterus, two methods of treatment are chiefly in use. One is the application of caustics twice a week to the diseased lining membrane as mentioned for the treatment of cervical catarrh. Now this plan is not altogether devoid of the risk of setting up peritonitis; it is very slow and uncertain in its results, as it must be persevered in for two or three months, and as the cervical canal is small most of the fluid in the cotton-wool gets squeezed out before it ever reaches the diseased endometrium. In my experience it is a far safer and speedier method of cure to give the patient ether, then, having rapidly dilated the cervix up to No. 14 Hegar, to thoroughly remove the mucous membrane down to the muscular coat with a curette. After this is done the uterine cavity is washed out with a hot 1 in 2000 perchloride of mercury solution passed in through a Budin's double catheter. A probe with dry cotton-wool is next introduced to absorb any blood in the interior of the uterus; this being withdrawn another probe charged with iodised phenol is quickly passed in and allowed to remain for two or three minutes. On its withdrawal a pencil of iodoform is inserted into the uterus and kept there by a couple of iodoform tampons in the upper part of the vagina. These tampons need not be removed for forty-eight hours unless there be considerable oozing, which is rare. I much prefer a sharp curette to the dull wire one recommended in books; it is more certain to thoroughly get rid of the thickened and diseased membrane, whilst with ordinary care no possible harm can be done. The after-treatment consists in keeping the patient in bed for ten or fourteen days and ordering an iodine douche (2 drachms to 2 pints) night and morning, at the same time prescribing a tonic with strychnine and ergot. As a rule, very little pain is felt subsequently, so that it is rarely necessary to administer a half-grain morphia suppository. Of the very many cases in which I have adopted the foregoing treatment, in not a single one has any pelvic inflammation ensued; in the great majority of cases the result has been eminently satisfactory. Some require a few intra-uterine applications subsequently, whilst in a small percentage the new endometrium also takes on a villous condition with recurrence of the hæmorrhage and necessitating a repetition of the curetting or, better still, intra-uterine application of electricity. That electricity is distinctly beneficial in some affections of the female pelvic organs, such as the disease we are now considering, some forms of dysmenorrhœa, &c., can only be doubted by those who have not given it a trial. As with all new methods of treatment, it has been said by some enthusiasts to be a cure for almost every disease peculiar to women, as uterine fibroids of all sizes, pelvic exudations, and even uterine cancer; but whilst such magnificent results have not been obtained at the hands of those who have given electricity a fair and unbiased trial, the two cases I am about to relate prove indisputably that its use is followed by most excellent results.

CASE 1.—A woman aged thirty-five was brought to me on Feb. 27th, 1894, by Mr. Coomber of Fakenham, Norfolk. She had six children, the youngest being six years old, and she had had no miscarriage. The patient complained of excessive loss at the periods, pain in the pelvis and over the left ovary, for the last two years, during which time she had been getting thinner and had been obliged to lead the life of an invalid. She had had yellow discharge in the intervals, which for the last three months had been offensive. The patient was a tall, somewhat cachectic-looking and emaciated woman. On examination the uterus was found to be bulky and tender and the cervix was hypertrophied. The sound passed four inches and caused pain and some little bleeding. Nothing abnormal was to be felt in the fornices. Chronic metritis was diagnosed, and I advised dilatation and curettage of the uterus. This was performed by me at the patient's residence in Norfolk. The mucous membrane was very much thickened and dark in colour. The two following periods were less in amount, and then all the old trouble gradually recurred. I advised a course of electricity, and this was accordingly carried out, the patient coming to London for the purpose. She was under treatment three months, and had altogether twenty-nine applications, with the result that she returned home feeling and looking a totally different woman. The periods became perfectly normal in every way, the loss being slight and accompanied with no pain. The uterus on bimanual examination felt much smaller and not the least tender, and the sound can only be made to pass barely two and a half inches. A few days ago I received a very grateful letter from this lady, in which she said she had not felt so well for many years, and that she was putting on flesh so quickly that she was almost afraid to be weighed.

CASE 2.—This was a woman aged thirty-one, who had been married twice and had had two children by her first husband, and none by her present one, to whom she has been married four years. Since her last marriage her periods had been getting excessive, with much pain and clots; the periods lasting seven instead of three days, and about thirty diapers having to be used. In the intervals there was almost constant pelvic pain radiating down the legs and into the back, a yellow inter-menstrual discharge being present. On examination the uterus was found to be bulky, low in the pelvis, the cervix lacerated, together with some follicular degeneration. The sound passed three inches and a half, causing pain and bleeding. I recommended that the uterus should be curetted, but the patient had such a dread of being anæsthetised that she refused to have the operation done. She agreed, however, to undergo a course of electricity, and this was accordingly carried out, with the result that in thirteen weeks the patient was completely cured. My last note is as follows: "The period just over lasted only four days; loss quite moderate, and unaccompanied by pain or clots; on examination the uterus is not tender on ballottement, feels less bulky, but is still rather low in the pelvis; the sound passes just three inches, and does not cause pain or bleeding. A ring pessary introduced in order to raise the uterus. The patient expresses herself as feeling greatly benefited by the treatment."

The method of applying the electricity is as follows. A vaginal douche of 1 in 2000 perchloride of mercury solution is given before and after each application. The patient being in bed and lying on her left side, the intra-uterine electrode, which may be of carbon or platinum (I prefer the latter), is introduced in the same way as an ordinary sound. The patient is now gently turned on to her back and the electrode kept in position by placing an unfolded towel against the end of the handle; the abdominal electrode—the best is, I think, a large carbon one covered with flannel—is soaked in a hot salt-and-water solution, the superfluous fluid is squeezed out, and the electrode applied to the abdomen. A piece of oil silk over it prevents the bedclothes from getting wet. The wires are now joined to a Leclanché battery, in connexion with which is a Gaiffe's galvanometer, in order that the exact amount of electricity administered can be accurately measured. Where a cauterising effect is desired

¼ in. to ½ in. in thickness, being bright-red in colour; it resembled the appearance of fresh blood-clot, only it had a membranous consistence; and on pressure between the fingers no crepitation or gurgling could be discovered. This I concluded must be the omentum. On raising the omentum upwards the cavity of the pelvis could be distinctly seen—the brim of the pelvis most distinctly so. The anterior vesical wall of the bladder was wanting, so that its cavity was fully exposed to the outer surface. The valve-like openings of the ureters could be seen, separated about a quarter of an inch from each other, in the floor of the bladder. There was no urethra, it being only a shallow groove leading forwards in the middle line to the pubis, where it terminated in a small gargoyle-shaped papilla which represented a rudimentary penis. The scrotum was developed in a fairly normal manner, but was perfectly empty so far as the testes were concerned. The anus was situated in its normal position. On July 7th the child's bowels were moved in the early morning, the discharge being meconial. Urine continued

Lower portion of trunk showing abdominal cleft with liver and cavit of bladder.

to be secreted, and soaked the piece of lint and absorbent cotton applied about the pubes. The hepatic tumour was very distinctly less, being reduced to half its former size, its lower border being level with the cleft in the abdominal wall. The omentum only projected downwards to the level of the bladder, and was of a light-red colour; its lower border was found to be continuous with the posterior wall or roof of the bladder, as the mucous membrane of the posterior wall of the bladder could be seen extending upwards to a level corresponding to that of the double fold of the omentum, in such a way that the peritoneal coat of the posterior bladder wall and the omentum were joined together, so that this membranous partition became a closed sac, enclosing and covering the bowels and other abdominal viscera. On the 8th the condition of the liver remained much the same. The child slept well most of the night, and was being fed with diluted milk sweetened with milk sugar. On the 9th slight irritation of the exposed parts around the bladder was noticed, and caused the child to cry frequently. The lower border of the abdominal cleft was painted with olive oil to modify the action of the urine. The milk sugar was stopped, and a weak solution (1 per cent.) of bicarbonate of soda was used instead along with the milk. The difficulty with the urine continued to be kept in check, but on the 14th the lower edge of the liver and the omentum presented an irritable appearance. Benzoated lard on lint was applied to the skin at the edges of the cleft to keep down the irritation. From the 15th, or the ninth day after the birth of the child, till the 21st, when the child

died, the irritation gradually gave place to ulceration and necrosis of the omentum, and also of the serous or peritoneal surface of the exposed portion of the liver, as it was utterly impossible to keep the exposed parts free from the action of the urine. The child became gradually comatose and died on the fifteenth day, tremors being frequent.

Remarks.—I have to state in conclusion a very remarkable fact regarding the action of cathartic remedies, which completely substantiates and confirms the classic experiments carried out by Rutherford on the lower animals, such as the rabbit—viz., by stimulating the exposed mesentery with various active principles of cathartic remedies and studying the peristaltic action of the bowel induced by their application. In the case just described I have actually on three different occasions—twice on the third day and once on the fifth day—applied by means of a fine camel-hair pencil a small quantity of castor oil to the omentum, merely flicking it over, with the result that there was evacuation of the child's bowels in from five to seven minutes, showing the speed with which absorption must take place in the abdominal cavity—far greater, in fact, than can be conceived. In every instance the motions were fluid and yellowish-green in colour. The engraving (which is from a photograph) represents the post-mortem appearances twenty-four hours after death. The position of the omentum and liver is very well shown, as is also the interior of the bladder, in the floor of which indications of the valve-like openings of the ureters can be seen. The other anatomical peculiarities are quite apparent. The sloughs on the omentum and surface of the liver appear to be lightish-grey in colour, as also the patches of slough on the edges of the abdominal cleft.

Hillhead, Glasgow.

SOME CONSIDERATIONS ON THE CHLOROFORM QUESTION, SUGGESTED BY THE REPORTS OF THE HYDERABAD AND "THE LANCET" COMMISSIONS.

BY T. LAUDER BRUNTON, M.D., F.R.S.

(*Concluded from page 89.*)

GROUP II.—DEATHS IN THE STAGE OF STRUGGLING.

In the second stage, the stage of struggling, death is more likely to occur from the effect upon the heart of simple choking than from any other cause. It is probable that struggling is usually induced by a feeling of suffocation, and that if the anæsthetic were sufficiently diluted, struggling would not occur. In this stage a certain amount of danger may also arise from the efforts of the assistants to restrain the struggles of a powerful patient because, in trying to keep him quiet, pressure may be inadvertently made on his chest or his respiratory movements otherwise interfered with. A practical but difficult question sometimes arises in this stage: whether to push the anæsthetic during this choking stage or to allow the patient partially to recover. Some administrators consider that it is best if the patient be strong and healthy rather to push the anæsthetic, so as to overcome the spasm which causes the choking, provided always that there is no obstruction to the passage of the air. Others prefer to stop the anæsthetic until the patient has got over the choking, and then to administer it again. There is more danger in this stage with chloroform than with ether, because with ether it seems necessary to produce a certain amount of asphyxia to aid its anæsthetic action. If ether is given along with a large quantity of air it is very difficult, at least in animals, to produce anæsthesia, but it is easily produced if asphyxia is brought about at the same time by limiting the supply of air breathed along with the ether vapour.

GROUP III.—DEATHS DURING THE STAGE OF ANÆSTHESIA.

During full anæsthesia deaths are most likely to occur from carelessness. It is very unlikely that deaths from shock should arise in this stage except in very rare cases. But even when the patient is thoroughly well under there seems to be a danger of reflex stoppage of the pulse through the vagus. This occurs in comparatively deep anæsthesia for operations on the eye, on joints, and sometimes for operations upon the intestinal canal, and especially upon the rectum, and urinary passages. There seems to be a tendency even during complete anæsthesia for reflexes to persist from these parts, so that both the respiration and circulation may be affected by the reflex irritation of these parts during complete anæsthesia. Anæsthesia thoroughly complete is very advisable in such cases. The chief danger in this stage seems to arise from the anæsthetist being present in body and absent in mind. His attention should always be undivided. With instruments and operations he should have no concern. If his attention is diverted to watching the operation he is apt to forget what is going on with the patient's respiration, and this is one of the causes of death from anæsthetics. They are alluded to in this report and cases. We had in the Hyderabad Commission some striking examples of this. The experiments were generally very successful, and though it was not always intended that the animals should be chloroformed to death, every now and again the animals died before the experiment was over with a curious regularity, when we did not want them to die. These unwished-for deaths did not occur in the morning, when the operators were all attentive, but generally in the afternoon, when the things were hurriedly put together and when the anæsthetist was not so attentive to his work as he might have been. They occurred more frequently when the anæsthetist who usually gave the chloroform was absent at the hospital, and when somebody else who was not accustomed to the duties was administering the drug. On two or three occasions with the ordinary anæsthetist deaths occurred, but this was only when we were doing something new in which he was much interested. He became engaged in watching the operator. The same thing happened to me when I was giving chloroform and doing an operation at the same time. We wanted to make some comparative experiments, and I was doing tracheotomy upon one monkey and another operator on a second. In attending to the operation I forgot to attend to the respiration, and allowed the chloroform to remain too long, and the animal died. The successful anæsthetist is the man who seems able to concentrate his attention most of all upon the patient and attends to nothing else. It is the man who attends to his own business and leaves other people's alone who is the most successful, and this is the best rule for the administration of anæsthetics.

HOW SHALL THE ATTENTION BE DIRECTED?

The next question which arises s the mode in which the anæsthetist's attention should be given. This is the point around which there has been great discussion—whether he is to attend to the respiration or to the circulation, or to both. It is interesting to inquire whether these clinical reports throw any light on this subject. The figures are given thus:

Statement.	Cases.
Cardiac failure	227
Respiratory failure	80
Simultaneous failure...	77
Total	384

Thus in all only 384 cases had statements appended regarding heart failure and respiratory cessation out of a total of 637 which have been noted, leaving 253 unaccounted for. But this report throws much light upon the conditions under which the "untoward" cases occurred in which recovery took place. On this point it is very definite. It says:—"The immediate symptoms of danger in these cases are practically in every case respiratory or circulatory. We are told that in a very large proportion of cases the respiration failed before the heart or pulse showed signs of flagging, and it will be seen that the measures adopted for resuscitation were in most cases those which were applicable to cases rather of cessation of respiration than to those of cardiac failure" (p. 1112). This is also borne out by the records of the administrations of the A.C.E. mixture. "Respiration appears in the majority of cases to have given out before the heart." These groups of cases are important as indicating that the detection of the respiratory failure at the appropriate moment led in nearly every instance to a catastrophe being averted. Now the evidence in favour of anæsthetics producing death from the respiration is this. In almost every case where anæsthetics pure and simple have been given by inhalation death is found to occur from the respiration, and the heart continues to beat for a considerable length of time afterwards. Chloroform injected directly into the heart, or driven into the lungs by

Digitized by Google

artificial respiration, would cause it to stop, but this could not be done by natural inhalation. The moment the chloroform begins to act upon the respiratory centres the respiration ceases, so that the anæsthetic cannot be introduced into the blood in sufficient quantities to stop the heart. What is to be feared is the combined action of the anæsthetic and of asphyxia.

In the face of this clinical evidence, supported as it is by a vast mass of experimental evidence, it seems to me that, if any choice has to be made between attending to the respiration and watching the circulation, only one answer can be given. My advice is: "Attend to the respiration and leave the circulation alone." The anæsthetist should not attempt to feel the radial pulse; but there is no objection to putting the fingers upon the temporal pulse, because it forms a convenient way of supporting the head of the patient. Without actually attending to the temporal pulse, if the finger rests upon the temporal pulse any changes which may occur will make themselves evident to the consciousness without interfering with the watch upon the respiration. If the pulse were to become flickering or to stop, one would at once detect it by the finger on the temporal artery, and might thus be led to examine the condition of the respiration before it was too late.

How to watch the Respiration.

There is sometimes a fallacy in watching the respiration, arising from apparent movements of the chest when there is very little air entering the lungs. It is advisable in all cases to hear the respiration. The patient may appear to be breathing very freely indeed while there is not a particle of air entering the lungs. It is possible for the upper air passages to be blocked by the tongue or by food getting into the larynx, or by the glottis becoming closed so that no air passes through it, and yet the movements of the thorax may be going on while the patient is dying from asphyxia the whole time. The only ways of ascertaining that air is entering the lungs freely are either to see the movements of the thorax and abdomen together or to hear the air entering and leaving the chest. The necessities of the operation often completely prevent both thorax and abdomen being seen together, and while the thorax is heaving the abdomen may become retracted or *vice versâ*. The entrance and exit of air from the nose and mouth may be heard by the unaided ear of the anæsthetist, or by the ingenious adaptation of a binaural stethoscope to the mouthpiece of an inhaler.

Group IV.—Deaths in the Stage of Recovery.

Of this group of fatalities some very interesting records have been tabulated, notably in Case 20, on p. 1114, and Case 57 on p. 1115, in which the patient laughed and talked after the operation. This ceased, and suddenly pulse and breathing were observed to have stopped. On p. 766, Case 162, it is recorded that "difficulty of breathing came on about one hour and a half after operation and no restorative measures were of avail." Many other instances of this form of dissolution are recorded. In the stage of recovery stoppage of the respiration has also to be guarded against, and the administrator has here to be particularly watchful that the air-passages are not stopped by fluid or solid matter passing down them, more especially as during this stage vomiting is apt to occur. Greater care has to be exercised in this respect towards the termination of the operation. An operation should not be done on a full stomach, because that organ when distended interferes with the respiration by its bulk as well as by its own weight. Further, a full stomach tends to give rise to vomiting, and the contents, when brought up, are apt to obstruct the air passages and thus prevent respiration or cause neuroparalysis. It has been advised to give a little brandy or some other stimulant shortly before the operation. In many cases this has done good. If the patient's circulation is much depressed this seems to be a useful thing to do, but in ordinary cases, and where the circulation is not exceedingly feeble, the patients are perhaps better without stimulants.

Group V.—Death some Days after the Operation.

In those cases in which death has occurred three or four days after the operation I have been unable to discover any means by which their occurrence may be foreseen and avoided. It has struck me that one cause of death may possibly be the poisoning of the individual by ptomaines formed in the body, because the mode of death in these cases is a very curious one. It occurs quickly, almost without any forewarning symptoms, and examination of the body reveals nothing but a little fatty degeneration of the heart. I have thought that these deaths were due to the presence of some poisons in the blood which had killed the patient, not primarily but secondarily, by fatty degeneration; that, in fact, these deaths might be looked upon as resembling deaths from phosphorus poisoning, in which fatty degeneration of the organs is caused by phosphorus. In those which occur several days after the administration of chloroform the fatty degeneration of the heart and death have been attributed to the action of the chloroform *per se*, but I have seen one case of death in a precisely similar way after the administration of ether. The idea that this fatty degeneration is due to some toxin may be regarded as fanciful, but it is at any rate worth while to observe cases, and especially cases of abdominal surgery, with a view to ascertaining its truth or falsehood.

Ptomaines and Fatalities.

The report throws some interesting light upon this by recording Cases 59, 60, and 61. During the operation the pulse became irregular and sank alarmingly. Nélaton's method was adopted with apparent success, and for a time the process had to be repeated four times, and the patient did not get over the symptoms of chloroform poisoning for three days. Case 60 recovered also after three days, and Case 61 after thirty-six hours. Among the untoward cases, after the administration of nitrous oxide gas, a similar occurrence (Case 2) is reported. The patient walked 400 yards to the station, and in the train was seized with a faintness, pallor, and active convulsion, became unconscious, and did not recover completely for several weeks. Professor Poehl of St. Petersburg told me that he had been making a number of investigations upon the urine, having special regard to the alkaloidal substances present in it, and he was able to tell by the condition of the urine whether an anæsthetic would be badly borne or not. As a rule, it was badly borne when a large number of alkaloids were present, but if there were few alkaloidal substances the patient could take the anæsthetic without fear. This would seem also to explain some other curious facts, such as that although a patient has taken anæsthetics well on several previous occasions he may yet die from the administration of the anæsthetic. From the report we learn that of the cases examined 11 males who died under chloroform had taken it safely once before; 11 females and 13 males more than once; and 1 is stated to have died from chloroform after having been under its influence on eight previous occasions. There is, of course, one cause of death that must not be overlooked. If the person has taken the drug three or four times without the least risk the operator or administrator may become careless upon the next occasion; but still it is quite possible also that the difference may occur in the individual and may depend upon something that the patient has had in his food or formed in his system.[1]

The Influence of the Geographical Position.

It has struck me a good deal when thinking over anæsthetics that in choosing one the decision depends a good deal upon the geographical position of the operator. Writers who live in the Northern States of North America state that ether is the anæsthetic which ought always to be employed. Those in the Southern States choose chloroform. Those who live in India, Egypt, and other hot climates will, as a rule, prefer chloroform. There is one marked exception to this general law, which is that in Edinburgh ether is very rarely employed, and chloroform has there always held its ground. On trying to make out why this should be I was at first sorely puzzled, because ether has one great disadvantage over chloroform in its irritating action upon the air passages. Ether tends to cause great secretion from the air passages and a rather severe bronchitic condition—so severe sometimes that some operators have given up its use on account of its after effects; and yet in cold countries, where this objection would tell more than in hot climates, ether is preferred. One reason of this, no doubt, is the difficulty of keeping ether in hot climates. But it occurred to me that it is just possible that the food of the people may have some effect upon the action of the anæsthetics, and it seemed to me that in Edinburgh there have been more fatalities of late years than there used to be. Now, there is one change which has come about within the

[1] Compare Experiments 31, 81, 84, 104–109, 119, 146, 147, 148, 156–161, 163, 164, 165, 170, 183, and 184 of the Hyderabad Commission.

Digitized by Google

last twenty years: the introduction of foreign meat has taken place, and large quantities—quantities which now are really enormous—are imported from America and Australia, so that meat-eating is much more common than before. More people eat meat, and those who were accustomed to eat meat seem now to eat more as a sort of general average per head. The consumption of meat per head has greatly increased within the last twenty years.[2] In hot climates people do not eat much meat, and even dogs do not get a chance of eating much meat, so that we must always remember that experiments made in hot climates differ not only in regard to warmth of the atmospheric air, but in regard to the food upon which the men and animals have lived, and I think it quite possible that many of the accidents which have occurred during the administration of chloroform have been due really to the condition of the patient as regards alkaloids present in the blood.

GENERAL CONCLUSIONS.

(1) Experiments on animals have conclusively shown that chloroform given by inhalation and not blown artificially into the lungs, kills by paralysing the respiration. (2) Clinical observation has shown that cases of simple danger without death during anæsthesia are due to failure of the respiration. (3) Cases of death may arise from the same cause, but may also be due to stoppage of the heart (syncope) or to stoppage of the heart and respiration together (neuroparalysis). (4) The most common cause of neuroparalysis has been found by Casper to be throttling, strangling, or drowning, which kill by neuroparalysis as often as by asphyxia. (5) Anæsthetics have no tendency to produce neuroparalysis except when they are given in such a manner as to irritate the respiratory passages either mechanically or chemically. (6) On the contrary, they tend to lessen shock. (7) During imperfect anæsthesia, both at the very commencement of administration of an anæsthetic and during recovery from its influence, choking may occur and cause death by neuroparalysis as well as by asphyxia. (8) The neuroparalysis is the result which is most to be dreaded, as simple asphyxia may be usually recovered from if artificial respiration be maintained. (9) It is therefore most important in the administration of anæsthetics to avoid anything which is likely to interfere with respiration, as such interference may act like throttling and cause death by neuroparalysis. (10) During complete anæsthesia, the reflexes being almost or entirely abolished, there is little risk of neuroparalysis, but the nerve-centres being weak there is more of asphyxia. (11) At the commencement of administration and during recovery, when the reflexes are present but may be deranged, the danger of death from neuroparalysis is greatest, and the respiration then requires to be watched with especial care. (12) Although there may be no objection to the anæsthetist keeping his finger on the temporal artery, and thus unconsciously watching the pulse, yet the respiration must be his main care, and anything that will withdraw his attention from it is studiously to be avoided. (13) The practical rules for administration, according to Syme and Lister, as given by Surgeon-Lieutenant-Colonel Lawrie in the Report of the Hyderabad Commission and in THE LANCET of Jan. 18th, 1890, are correct.

THE DIAGNOSIS OF SMALL-POX.

BY H. MEREDITH RICHARDS, M.D., B.S. LOND,
MEDICAL SUPERINTENDENT, CITY HOSPITALS, BIRMINGHAM.

ACCURACY in the diagnosis of those infectious diseases which are notifiable to the sanitary authority has now acquired an importance which it is difficult to over-estimate. The majority of well-regulated communities have not only adopted the Notification Act, but have provided special isolation hospitals for the treatment of small-pox. It is the common experience of all such hospitals that from 5 to 10 per cent. of the cases notified as small-pox are really the victims of some other disease. These cases of "wrong diagnosis" are a source of grave anxiety to all concerned. They cast a serious responsibility on the hospital staff. They are even more annoying to the practitioner notifying the case, who, according to recent experience in Dublin, may find himself the defendant in an action for damages. Almost equally harassing is the mischievous gossip which arises from that section of the public which appears not only to expect, but to demand infallibility from their medical adviser. Failure to recognise and notify a mild case of small-pox may lead to even more disastrous consequences, as, in addition to the risk of an action for not notifying, there is the possibility of the undetected case giving rise to a house epidemic and possible grounds for an action for damages incurred thereby. During the last three years I have had exceptional opportunities in Birmingham and elsewhere of realising the responsibilities and difficulties involved. Not only have over 3000 cases been sent to the hospitals of which I have had charge, but it has been my lot to visit, on behalf of the medical officer of health, every case notified as "possible small-pox." It may not be out of place to remark how very much more easy it is to avoid friction in revising a diagnosis if the case is seen at the patient's own home. There is no unpleasant dread that the patient may have been exposed to infection, and there is no grumbling about injury to health from removal to hospital. In those frequent appeals to the Local Government Board as to the right of the medical officer of health to visit notified cases, no distinction is made between those diseases which it is intended to isolate in hospital and those which are to be treated at home. There can be no doubt among those who have had any experience that visiting the former cases before removal greatly facilitates the working of the Notification Act. If the case goes to hospital the diagnosis has to be revised, and this revision can be far more pleasantly and far more conveniently done at home.

Errors in the diagnosis of small-pox are readily explained. Apart from the intrinsic difficulties occasionally involved general practitioners are further hampered by the fact that small-pox has become a comparatively rare disease, while those cases which do occur are hurried off to special hospitals where only a limited number of men have the opportunity of studying their clinical history. The following notes are the result of a study of some 500 cases in which a provisional diagnosis of small-pox was referred to me for revision, and are written with full appreciation of the difficulties of those who find themselves betwixt a very Scylla and Charybdis while endeavouring conscientiously to discharge a legal obligation and a public duty.

My list of "wrong diagnoses" includes in order of frequency varicella, measles, scarlet fever,[1] erythema exudativum, syphilis, acne vulgaris, sweat eruptions (especially sudamina), impetigo contagiosa, influenza, psoriasis, urticaria, generalised vaccinia, vaccinia lichen, varicella gangrænosa, papular eczema, pemphigus, rötheln, glanders, scabies, purpura, folliculitis, antipyrin rash, iodide rash, herpes zoster, herpes facialis, sycosis barbæ, and no obvious disease. It would hardly repay to discuss the differential diagnosis in each of these diseases. It must be remembered that during most of the time during which my notes were made, small-pox was epidemic, and certain provisional diagnoses were due to very excusable panic—e.g., acute psoriasis, herpes facialis in the course of continued fever, sudamina in rheumatism, and so forth. In many cases the fatal omission to *see all the rash* was responsible for the opinion arrived at. This was especially true of varicella. Most common of all, perhaps, was absolute reliance on the presence or absence of some particular so-called "pathognomonic sign"—e.g., umbilication, pain in the back, or what not. The diagnosis is best discussed in relation to the various stages of the disease, and I shall adopt the very convenient convention of the Clinical Society[2] of limiting the term rash to the initial erythemas and purpura, while "eruption" is reserved for the true variolous exanthem.

1. *Diagnosis in the pre-eruptive stage.*—A combination of vomiting, pyrexia, and lumbar pain can be regarded only as suggestive, but would be highly suspicious if small-pox were prevalent and would certainly justify isolation of the patient and vaccination of those associated with him if there were a definite history of exposure to infection about twelve days previous to the onset of symptoms. In most cases a certain diagnosis will be made on the appearance of the eruption, though in very rare cases there is no exanthem.[3] As regards

[2] A friend informs me that the increase in twenty years from 1873 to 1893 amounts to 13½ per cent.

[1] Here the error was, except in one case, that of mistaking small-pox for scarlet fever.

[2] Supplement to Transactions, vol. xxv., p. 178.

[3] These cases of variola sine variolis are very puzzling. If presenting typical symptoms and occurring after exposure to infection they should be isolated and revaccinated.

Digitized by Google

the prodromal rashes, the general scarlatiniform rash gives rise to most trouble. In about a dozen instances this variety has been diagnosed as scarlet fever and sent to hospital as such. As far as the rash itself is concerned it is often absolutely indistinguishable from scarlet fever, while pyrexia and vomiting are common to the two diseases. Severe lumbar pain[4] and epigastric pain are greatly in favour of small-pox, especially if circum-oral pallor, strawberry tongue, and adenitis are absent. The condition of the throat is of most importance. In small-pox at this stage the throat is either unaffected or one finds a varying number of bright-red macules[5] about the size of a split pea scattered over the soft palate and pillars of the fauces. This is very typical and quite different from the œdematous injected arch seen on the palate in scarlet fever. More typical still is the appearance of opaline vesicles in the same region. Careful examination of the throat will, at any rate, arouse suspicions of small-pox. Morbilliform prodromals are often mistaken for measles, but these rashes are rarely seen on the face, are not so papular as measles, and are not accompanied by catarrhal symptoms. Urticarial prodromals are fortunately uncommon. They are extremely deceptive, and a certain diagnosis can only be made after the appearance of the eruption. It is important to remember that a prodromal may take this form. If a patient who has been exposed to the infection of small-pox develops pyrexia, with an urticarial-like rash, he should certainly be placed in quarantine to watch developments. The so-called "bathing-drawers" rash, which may be erythematous or petechial, and is confined to the groins and axillæ, affords certain grounds for diagnosing small-pox if accompanied by the ordinary symptoms of that disease.[6] The diagnosis of purpura variolosa is very easy if the existence of this type is borne in mind. The rash may not be distinguishable from ordinary purpura, but is usually accompanied by the petechial "bathing drawers" rash. This, combined with more or less pyrexia, hæmorrhages from mucous membranes, hæmorrhagic chemosis of the ocular conjunctiva, extreme pigmentation of the lower eyelids, slight lividity, complete consciousness, with a general aspect of intense weariness and prostration, form a clinical picture which can hardly be mistaken.[7]

2. *Diagnosis in the early eruptive stage* (*i.e., stage of papules and papulo-vesicles*).—The eruption usually appears on the third day, is distinctly shotty on the fourth, and vesicular on the fifth day of the disease. Any eruption following constitutional symptoms which has this course is very probably small-pox, and is almost certainly so if the eruption is accompanied by a fall in temperature, if it is most marked on the wrists and face, if the developed papulo-vesicles are about the size of a split pea and of a greyish-blue colour.[8] A small-pox eruption is for the most part uniform in development except that the lesions appear earlier on the wrists and face than on the trunk and legs. The subsequent evolution of the rash follows the same course, so that vesicles on the wrist or face may be accompanied by papules on the legs. Some of the vesicles will usually show umbilication, but far too much importance has been attached to this sign, which is frequently absent altogether. Measles is frequently taken for confluent small-pox and *vice versâ*. Attention to the following distinction will prevent mistake. The eruption of small-pox most commonly appears on the second or third day, that of measles on the fourth or fifth day of illness. Coryzal symptoms of measles and especially a laryngeal cough are absent in small-pox. The temperature tends to fall in small-pox, but rises in measles as the eruption develops. The condition of the soft palate and fauces is very different in the two diseases; in measles there is general injection combined with mottling, while in confluent small-pox there are flat opaline vesicles or at any rate the red macules previously described.[9] Too much dependance is perhaps placed on "Griselle's sign"; small-pox is not shotty in the first few hours when it is most likely to be mistaken for measles, and measles papules can occasionally be just felt when the skin over them is stretched. In case of doubt time will solve the problem, as after the lapse of twenty-four hours some of the papules will have become vesicular if the disease is small-pox.[10] Typical varicella, in which the clear superficial vesicles look like drops of water, has little resemblance to any stage of small-pox. The eruption is evidently quite superficial in chicken-pox, apparently not deeper than the Malpighian layer of the epidermis, while in small-pox the true skin is usually involved. Constitutional symptoms are little marked as a rule in chicken-pox, while they are rarely absent in small-pox. Too much reliance cannot, however, be placed on this. A temperature of 102° to 103° F., with some backache and vomiting, is quite compatible with an uncommonly severe case of varicella. The eruption is usually the first symptom noticed in varicella. It differs from small-pox in being most marked on the trunk, and comes out in irregular crops instead of having the orderly progression noticed in small-pox. It is distinctly vesicular from the very first day, and as the disease advances it exhibits a medley of papules, vesicles, pustules, and scabbing lesions in every part of the body. Umbilication[11] is occasionally seen, and appears to depend on accidental relations to sweat glands or hair follicles, but is very rare apart from the pseudo-umbilication referred to later. One is sometimes asked, Could not a given varicella eruption be modified small-pox? Abortive small-pox vesicles always exhibit a typical infiltrated papular base, which is absolutely distinct from the hyperæmic areola of varicella. It may be repeated that most mistakes are due to not seeing the whole eruption.

Papular syphilides are occasionally diagnosed as small-pox, but the different constitutional symptoms, the onset, the polymorphic character of the rash, cachexia, general glandular enlargement, and primary sore are sufficient to make the distinction once suspicion is aroused.

3. *Diagnosis in the late eruption stages; vesico-pustules and scabbing lesions.*—Varicella is again the stumbling-block. Polymorphism and history of symptoms and development are again all important. It cannot be too strongly insisted that early papules and scabbing lesions are never contemporaneous in small-pox, though frequently so in chicken-pox. Typical scabbing varicella lesions are common between the scapulæ and on the loins. Such a lesion is irregular in outline, varies in diameter from one to three lines, has a central depressed scab[12] consisting of dark brown or almost black sugary-looking dried serum, and is quite unlike the yellowish smooth scab seen in unmodified small-pox, and is still more unlike the reddish-brown circular discoid scab found on the apex of a papule in abortive small-pox. It need hardly be pointed out that the scarring consequent on the two diseases is very different, but I have known the diagnosis of chicken-pox to be doubted because a certain amount of subsequent scarring resulted. Scarring in chicken-pox appears to be due to a secondary ulcerative process, and not to the lesion being primarily situated in the cutis vera. This ulceration leaves irregular, pigmented, flat, smoothed, punched-out depressions, instead of the foveated or conical pits seen after small-pox.

The diagnosis from acne vulgaris is occasionally difficult, but the pre-eruptive symptoms, uniformity of rash, presence of lesions on the scalp, wrists, and the palate, and absence of comedones will usually clear up any doubt. Great care is needed to avoid missing mild small-pox occurring in a patient already suffering from acne. I have a very lively recollection of being misled by such a

[4] A certain amount of back-ache is of course common in most pyrexial conditions, and severe lumbar pain is absent in about 50 per cent. of all cases of small-pox.

[5] These macules subsequently develop into the flat, opaline vesicles of small-pox. The endanthem is never distinctly papular, and the vesicles are at most very slightly raised above the general surface of the mucous membrane.

[6] Very occasionally scarlet fever patients exhibit a marked concentration of rash on the lower part of the abdomen and groins. In these cases the throat, tongue, and adenitis settle the diagnosis.

[7] Undiagnosed hæmorrhagic small-pox has often been the starting point of a localised epidemic. I remember one such case which was certified as death from "German measles." Some friends from a distance who attended the funeral developed small-pox twelve days later.

[8] This is generally very well seen in the vesicles on the wrist. They are absolutely different from the straw-coloured vesicles of varicella. The difference in colour is due to the varying thickness of the epidermic roof of the vesicle.

[9] A minutely granular condition of the soft palate is not uncommon in measles, and indeed in health, but should not be confused with the macules and vesicles of small-pox. As already stated, raised papules are practically unknown on the palate in small-pox.

[10] For practical purposes measles may be said never to become vesicular. So-called vesicular measles is of the nature of an epiphenomenon, and consists of minute miliarial vesicles occurring in rare cases at the centre of the papules.

[11] Absence of umbilication appears to depend on varicella vesicles being altogether in the epidermis proper, where there are no strands of tissue, epithelial ducts, and so forth, to tie the vesicles down.

[12] This pseudo-umbilication is a very common source of fallacy, as Dr. McVail recently pointed out. (Journal of State Medicine, vol. i.) True umbilication may, however, undoubtedly be seen in varicella.

Digitized by Google

combination, and not being set right until typical small-pox lesions made their appearance among those of acne. The rash of glanders *per se* is certainly very like pustular small-pox, and vomiting and pain in the back are common to the two diseases. In glanders, however, the eruption does not appear till well on in the second week; it comes out in crops, very rapidly pustulates,[13] and is generally distributed without any predilection for face and wrists. More important than all, glanders is a discrete eruption, but exhibits constitutional symptoms as grave as if it were confluent small-pox. Once glanders is suspected, the history of association with horses and, if needs be, a bacteriological examination will clear up the case.

The only case of iodide rash with regard to which I have notes of any difficulty was in the instance of a patient suffering from acute Bright's disease. The renal pain and vomiting of nephritis simulated small-pox, but the grouped pustular eruption situated on an inflamed base was easily recognisable as due to iodide or bromide. Inquiry soon elicited the fact that he had been taking iodide of potassium for chronic pleural effusion.

It is customary to lay stress on the vaccinal state as affording presumptive evidence. Personally, I prefer to be unbiased and make up my mind apart from any such consideration, as it is impossible to lay down any absolute rule as to the duration of the immunity enjoyed by the vaccinated. Still, it may be remembered that a copious vesicular eruption in a well-vaccinated child or occurring more than fourteen days after revaccination is very unlikely to be variola. Vaccination rashes, especially vaccinia lichen, are now and then mistaken for small-pox. More important is it to remember that successful vaccination performed a few days previously to the appearance of a given eruption does not exclude small-pox. I have notes of one such case in which the presence of normal vaccine vesicles led to the diagnosis of generalised vaccinia—a diagnosis which was even maintained when the "cow-pox" spread to several members of the patient's family. It is not, however, my intention to dwell on my own or on others' mistakes. "We are none of us infallible, not even the youngest of us," and I will conclude by bearing my ungrudging testimony to the conscientious and unselfish way in which the members of our profession have endeavoured to aid the sanitary authority by the early notification of small-pox. Early notification is of vast importance in prophylaxis, but adds immensely to the difficulties of those on whom the responsibility is made to rest.

Birmingham.

ON THE CAUSE OF ROTATION IN SCOLIOSIS.[1]

By C. B. KEETLEY, F.R.C.S. Eng.,

SURGEON TO THE WEST LONDON HOSPITAL AND TO ITS ORTHOPÆDIC DEPARTMENT.

It is acknowledged by all except a few pathologists who would seem never to enter a museum that the peculiar shape of the scoliotic spine is almost entirely the sum of changes in its component vertebræ—i.e., it is only in a small degree the result of changes in the ligaments and articulations. What are the changes in an individual vertebra? They are greatest in a certain very small number, chiefly those at or near the centre of each curve. They have been many times described; for example, by Bouvier, by Nicoladoni, and by Lorenz, the last two authorities having in their minds during the description each a special theory to account for the "rotation." Lorenz's description is very minute. If we look at the front of a vertebra chosen from the centre of a curve with convexity to the right, we should expect to find the outline of its body wedge-shaped, with the apex towards the concavity of the spinal curve, and more or less marked, with a horizontal groove on the left side, as if the force of growth, having been checked perpendicularly, had spread laterally, so as to form two lips. If the same vertebra be viewed from behind it will probably be found that, although not strictly symmetrical, especially as regards the articular processes, the wedge-shape is not at all pronounced, and may even be not discoverable except by measurement. If, now, a third view be taken of the vertebra—viz., from above—it will, if at all a typical case, be seen to be strangely "slewed," as it were, in such a manner that the posterior segment of the vertebra, including the pedicles, the transverse processes, the laminæ, and the spinous processes, appear to have struggled to retain their normal relations and positions in the particular human frame to which they belong, while the body of the vertebra has been equally determined to deviate to the right. "Struggle" is, in one respect at least, a good word, because it suggests a certain amount of confusion, such as might produce the minor varieties in the pathological anatomy of such bones as I am describing. But the chief peculiarities are both orderly and almost uniform. If it be granted that the prime cause of scoliosis is, in young children, ordinary rickets, and in older ones and in youths "rachitis adolescentium," it cannot be forgotten that in rickets it is at the so-called "epiphysial" cartilages that the greatest abnormality of growth, leading to the major part of each rachitic deformity, takes place. Now the epiphysial cartilages of the vertebral body are placed above and below the main bony masses, but the cartilages of growth of the transverse processes and the spinous process, and in fact of the whole segment of the vertebra posterior to its body, are placed horizontally with regard to one another. There is also the equivalent of an epiphysial cartilage in each vertebral body near the root of the pedicle. Hence rachitic deformity would have a much greater tendency to produce lateral inclination in a vertebral body than in the more posterior constituents of the vertebra. Further, the external projection of the transverse and articular processes gives them an increased mechanical power, like that of buttresses and of cross-trees, to check a tendency to lateral inclination. On the other hand, the comparative thinness from side to side of the pedicles, arches, and spinous processes offers diminished resistance to horizontal "slewing" of those parts. Therefore, the fact that the layers of cartilage of growth or epiphysial cartilages above and below each vertebral body do not extend backwards to the posterior parts of the vertebra is the prime cause of torsion, and the arrangements of the cartilage of growth of the pedicles, transverse and spinous processes, together with their shape, greatly contribute to the production of torsion by facilitating "slewing" of these parts in a horizontal direction. The only explanation of torsion which I have been able to find at all analogous to that just given is Lorenz's. He finds the cause of torsion in the existence of the cartilage of growth in each side of the posterior part of the vertebral body near the base of the corresponding pedicle. That this is a most important factor I grant, but I think it causes, not the torsion, but the great degree to which torsion may reach. It is a specially important fact that near the junction of the anterior with the posterior segment of each vertebra there is a cartilage of growth which is, like others of its kind, no doubt specially sensitive to rachitic influences. But I maintain that unless the vertebral bodies had their principal cartilages of growth placed above and below them, they would have no more tendency to lateral curvature than the rest of the vertebræ, and therefore the action of the pedicle cartilage would not come into play.

Grosvenor-street, W.

[13] In one case of which I have notes it was pustular on the third day.

[1] A paper read at the opening meeting of the British Orthopædic Society on Jan. 31st, 1895.

NOTE ON THE LIMERICK POISONING CASE.

By SIR CHARLES A. CAMERON, F.R.C.S. Irel., D.P.H.,

MEDICAL OFFICER OF HEALTH OF DUBLIN.

On July 3rd, 1895, about seventy inmates of a convent and boarding-school in Limerick became very ill after dinner, and for several days suffered from vomiting and purging of a severe character. Three ladies died and many of the other inmates were for several days in a precarious condition. Poison being suspected, portions of the vomited material and dejecta were sent to me for examination on July 5th, together with a portion of corn-flour which it was suspected might contain poison, but none was detected in it or in the other matters sent to me. Suspecting the case to be one of ptomaine poisoning I telegraphed for portions of everything the

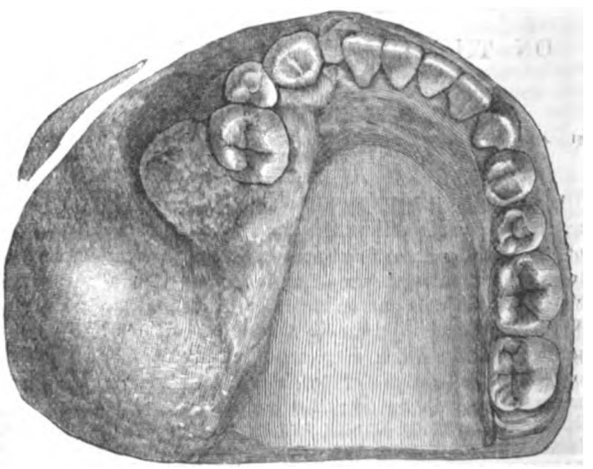
Digitized by Google

patients had had for dinner, but the only items available were sugar and sodium bicarbonate, both of which were pure. It has been clearly ascertained that the poison was not in the meat used, for some persons who had partaken of it were not ill, and the history of the carcass that furnished it was made out and negatived the hypothesis of unsoundness or disease in it. It appears that a custard formed part of the dinner and that all who partook of it sickened. The cook (one of the sufferers) states that she prepared the custard as follows: "Tuesday, July 2nd: Took four quarts of skimmed milk of previous night, boiled it, added about half a pound of loaf sugar, added two tablespoonfuls of cornflour and boiled again. This was done in a tin vessel. 3 or 4 P.M.: Resumed making of custard; beat up eight or ten eggs, all fresh except one which had a reddish-brown colour but no bad smell, poured them into milk which was then about the temperature of tea, and then poured into earthenware bowl; removed to a cold place during night. Wednesday, 3rd, 9 A.M.: Custard had become quite thin, of consistence of cream; poured it over seven or eight quarts of strawberries, about one and a half quarts of which had been gathered on previous night, whipped the whites of eggs used above, with one pound of sifted sugar and spread over strawberries and custard on glass dishes." That the strawberries were the cause of the illness is negatived by the fact that three or four persons who took gooseberries and not strawberries with the custard were amongst the sufferers. The inquiry is therefore narrowed to the question, Was the *materies morbi* in the milk or eggs. It would seem that some surprise was manifested by the custard remaining thin. When I first heard of this fact I thought the fluidity might be due to the liquefying influence which certain bacilli have on gelatine and albuminous matters, though the rapidity of their action in this particular case seemed surprising; I therefore had a custard made similarly to that described by the cook, and found that it remained as thin as rather thin cream. This want of consistency was, however, due to the albumin of the eggs not having been coagulated by heat, for when my custard was heated to near the boiling point (as should always be done) it became on cooling quite thick. That a highly poisonous substance (tyrotoxicon) is generated in milk (not necessarily very stale) is well known. In the Limerick case the milk was at least two days old when consumed, as at eleven o'clock on the previous day it was skim-milk of "the previous night." It was, however, boiled, and after the addition of cornflour and sugar again boiled. The question is, Could the milk in the presence of sugar and cornflour have generated tyrotoxicon from the time it was boiled at eleven o'clock on Tuesday until it was produced at dinner at one o'clock on Wednesday? The time of the year was favourable to the fermentation of the unstable mixture. The temperature of the mixture was favourable to incubation of micro-organisms. Suspicion falls more strongly on the eggs. I have learned that they were market eggs, and had been purchased four or five days before they were used. Though not putrid, they were more or less stale, and one had a curious colour, described by one person as resembling that of claret. Now after the addition of the eggs to the luke-warm milk, sugar, and cornflour, there was no further heating, and it is clear that the egg albumin was not coagulated. There is reason to believe that the discoloured egg was cracked, and if so micro-organisms had access to its interior. The viscera of two of the patients who succumbed to the attack were examined for ordinary poisons, with negative results. A substance was extracted from them which gave all the characteristic reactions of ptomaines. The quantity available for examination was altogether insufficient to differentiate the ptomaine or ptomaines present from others of which there seems to be a very large number. I am not aware that in any case of ptomaine poisoning the ptomaine was extracted from the viscera and identified. In this case it is much to be regretted that neither the custard nor the matter ejected from the patients on the first or even second day of their illness was available for bacteriological and chemical examination. A fourth patient died yesterday, and there is only one now whose state causes anxiety. The inquest was held yesterday, and the verdict was in accordance with my evidence.

Dublin, July 17th.

ST. THOMAS'S HOSPITAL.—The Corporation of the City of London has granted a donation of 200 guineas to the special fund for the closed wards of this hospital.

ON THE MECHANICAL TREATMENT AFTER PARTIAL EXCISION OF THE LOWER JAW.



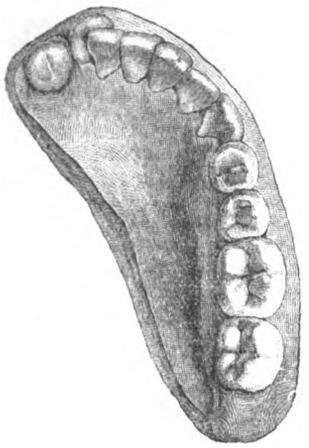
BY F. NEWLAND-PEDLEY, F.R.C.S. ENG.,

DENTAL SURGEON AND LECTURER ON DENTAL SURGERY, GUY'S HOSPITAL.

No great difficulty is experienced in artificially restoring portions of the jaw lost from disease or removed in surgical operations, provided that sufficient bone be left to maintain the dental arch and give support to a denture. Even when a large fragment of the jaw, including the base, is lost from necrosis, we may hope that in a young patient the bone will be reproduced, and the treatment consists in holding the fragments at rest by means of a splint whilst repair is progressing. The most difficult cases, however, are those in which it becomes necessary to remove the ascending ramus or half the jaw in order to arrest a malignant growth, for the remaining fragment quickly undergoes remarkable displacement, falling inwards until it rests upon the tongue, and occupying a position in the median line of the mouth. Here, as a rule, it becomes fixed by cicatricial tissue, rendering the jaw useless as a masticatory organ and occasioning great permanent deformity. Few of these cases have come under my treatment during fifteen years of hospital practice, and doubtless excision of large segments of the lower jaw for advanced malignant growths in elderly patients only prolongs life for a time, and mechanical treatment is not attempted. This, at least, has been my experience, for I cannot recall a single previous case in which treatment was commenced early enough to be successful; the rest, without exception, were failures, because the remaining segment of the jaw was firmly fixed, the muscles were shortened, and further surgical operation seemed contra-indicated. Unsatisfactory results could be averted if the dental surgeon was consulted before the bone became fixed, as may be proved by a case recently treated at Guy's Hospital.

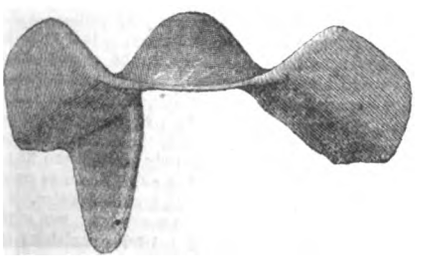
A girl aged twelve years was admitted under Mr. L. A. Dunn for a large sarcoma of central origin, situated in the left side of the lower jaw, extending backwards to within half an inch of the sigmoid notch and forwards to the second bicuspid tooth. The annexed model of the growth (Fig. 1)

FIG. 1.



was taken by Mr. Parfitt, who was dresser to the case. The whole of the ascending ramus was removed and nearly half the body of the jaw, reducing the dental arch to the limit indicated in Fig. 2. The wound healed rapidly, and Mr. Dunn, foreseeing the deformity that would necessarily result from the operation, transferred the patient to my care for mechanical treatment some ten days after the operation. I then found the characteristic displacement, which, however, yielded to pressure; but it was clear to me that any contrivance to keep the lower jaw in place must take its fixed point from the upper jaw, for no continuous pressure should be applied over the recent wound. I therefore made a Gunning splint which covered

Digitized by Google



the upper and lower jaws, uniting them together; but the contrivance was unsightly and would have been a great impediment to mastication; so, after several attempts, I made a modification of Gunning's splint by covering the upper jaw with vulcanite and gold, and affixing to it a shield of vulcanite passing almost vertically downwards and preventing the lower jaw from deviating inwards when the mouth was opened to an ordinary extent. The patient can

FIG. 2.

remove the plate easily, and can replace it by pushing the jaw into the shield with her finger. She can now masticate her food satisfactorily and is looking in good health. In constructing one of these contrivances for a child twelve years of age it must be remembered that the jaw is far from fully developed, and allowance must be made for erupting teeth; on the other hand, the erupted teeth must be kept in their positions by antagonising with the plate, or they will rise unduly in their sockets. The age of sixteen is usually

FIG. 3.

considered quite early enough for a patient to wear a denture, and I purpose retaining the use of the present contrivance for about four years. At the end of that period I shall probably find some dense cicatricial tissue occupying the site from which the bone was removed, and this may prove firm enough to support a denture and keep the right side of the jaw in place. Fig. 3 is from a drawing of the plate now worn.

Devonshire-place, W.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of directors of the society was held on July 10th at 8 30 P.M. Sir James Paget, President, took the chair. One fresh application for a grant was read from a widow and assistance given. The death of a widow had occurred who had received grants since June, 1877, and had had £1247 in all, her husband having paid thirty-eight guineas to the funds of the society. One new member was elected and the deaths of two were reported. A sum of £1264 was voted to be distributed among fifty-three widows, nine orphans, and four orphans on the Copeland Fund. A grant of £52 10s. was made to a widow under By-law 70. A legacy of £200 Stock, duty free, was announced from the executors of Dr. Bissett Hawkins. The expenses of the quarter came to £62 11s.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON A HEAVY BRAIN.

BY GEORGE COWIE GRANT, M.B., C.M. ABERD.,
JUNIOR ASSISTANT MEDICAL OFFICER, BIRMINGHAM CITY ASYLUM, RUBERY HILL.

AT a post-mortem examination recently made at the Birmingham City Asylum, Rubery-hill, a brain of very large dimensions was examined. It belonged to a man aged forty-three, who suffered from epilepsy for seven years and died from congestion of the lungs following upon a succession of fits. He was admitted to Winson-green Asylum in April, 1892, suffering from epileptic dementia, and was in January, 1893, transferred to Rubery-hill. His sister stated that the fits began about seven years previously, and occurred for some time only at long intervals; that prior to his having fits and for some time afterwards he was a very intelligent man, much given to reading books and discussing politics. He had been fairly strong, but suffered from periodical headaches. Occasionally he went in for heavy drinking bouts. The necropsy disclosed the following. The circumference of the head above the eyebrows was 25⅝ in. The bones of the skull were not unduly thickened. The dura mater was thickened throughout, and at several points was firmly adherent to the skull-cap. The falx cerebri was ossified from its attachment to the internal occipital protuberance as far forward as the fissure of Rolando. The pia arachnoid was milky and opaque and as thick and tough as an ordinary dura mater, while its vessels were varicose and tortuous. It was adherent to the brain in several places, but mostly so in the frontal region. Recognising that weighing a brain with so thickened a pia arachnoid would give quite an erroneous idea of its real weight, the membrane was removed with as little brain substance adherent as possible. Clear of all membranes and free from all fluid—as it was afterwards found that the ventricles contained none—the brain weighed sixty-seven ounces. The convolutions were plump and well-formed. To the naked eye and microscopically no pathological changes were evident in the organ except an enlargement of both choroid plexuses of the lateral ventricles and a partial ossification of the left one. In the free extremity of this plexus several delicate plates of bone were deposited. I might here remark, from what I have observed myself and from what I have learned from men of long experience in asylums, that it is the practice in many asylums to weigh the brain with the pia arachnoid attached. Had such a method been followed in this particular case quite an erroneous result would have been arrived at, as the pia arachnoid scaled four ounces. It would be interesting to know whether the brain weights published in THE LANCET of June 15th are the weights of the brain alone or the brain *plus* membranes.

Rubery-hill.

A CASE OF SULPHONAL POISONING IN A DIPSOMANIAC.

BY W. WRIGHT HARDWICKE, M.D. ST. AND.

A MARRIED woman, aged thirty-seven, separated from her husband owing to her habits of intemperance, had been abstemious under moral restraint for about three months, when, on May 24th, 1895, she showed signs of an approaching attack of alcoholism. She was watched carefully for a time, but owing to illness and removal of her attendant she was left in charge of a maid. Her first dose, on June 1st, was about one pint and a half of methylated spirit, partly procured from a lamp in the house; then two-pennyworth of the same was obtained from a lamp shop (about six ounces), the druggists in the district having received notice not to serve her; thereupon, her thirst seemed to be so extreme that she

Digitized by Google

resorted to some painters, from whose can of turpentine she took a drink. She next discovered a bottle containing 100 tabloids of sulphonal, containing five grains in each, which had previously been taken from her, and which she had received by post; these she chewed up in her mouth one after another till she had swallowed fifty-three (equal to 265 gr.). About 5 P.M. the same day she was found by the maid (who had unfortunately been obliged, owing to domestic duties, to leave her a great deal to herself) in a state of stupor on the floor, and was carried to bed. At 11.15 P.M. I was summoned to her, and found her sleeping on her side with her knees drawn up, and the pupils slightly contracted and insensible to light. When roused she smiled graciously and lapsed off to sleep again; she tried once to raise herself in bed, when she fell powerlessly back again. Next day the legs were found to be extended, and the soles of the feet were arched in a state of extreme flexion. The bowels were confined. She slept from 5 P.M. on June 1st till 5 A.M. on the 4th—sixty hours—and did not regain speech till the 7th and the power of locomotion till the 9th. This case is interesting as showing the irritation produced to the plantar branches of the post-tibial nerve—presumably by the sulphonal—and the long period that elapsed before the toxic flexion of the soles made itself manifest, thus showing the slowness of the action of the drug.

PAROSTEAL LIPOMA CLOSELY RESEMBLING A PERIOSTEAL SARCOMA OF THE FEMUR.

BY FREDERICK PAGE, M.D. EDIN., M.R.C.S. ENG.,
SURGEON TO, AND JOINT LECTURER ON CLINICAL SURGERY AT, THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

IN Mr. Bland Sutton's work on Tumours nine reported cases of parosteal lipomata are referred to. Another has just come under my observation. A woman some five-and-forty years of age showed me a few days ago a swelling on the inner side of the lower end of the right thigh, which she told me she had noticed slowly growing for about four years. It was evidently closely connected with the bone; the superficial veins over it were enlarged, and the swelling closely simulated a periosteal sarcoma. It turned out, however, to be a parosteal lipoma about the size of a flattened goose-egg, encapsuled, and so closely connected with the periosteum that it could not be separated from it. The case is worth recording for more reasons than one. I know of only one other example of parosteal lipoma of the femur—namely, that recorded by Mr. D'Arcy Power in the Transactions of the Pathological Society of London. The great interest of the case I am reporting, however, lies in the resemblance the tumour bore to a sarcoma—a resemblance which might have led to amputation of the limb instead of the removal of the growth.

Newcastle-upon-Tyne.

A MEMORIAL BED.—On Monday, July 15th, a meeting of the Ladies' Association of the Great Northern Central Hospital was held in the board-room, the occasion being the presentation of a bed endowed with a sum of £1050 by the Ladies' Association to Dr. William Cholmeley, the consulting physician to the hospital, in appreciation, as the commemoration plate says, of "many years' devoted and unselfish labour." The present building originated in a little private hospital started in 1856 by Mr. F. S. Statham, which was taken over by a committee of management in 1857. Dr. Cholmeley was one of the first members of the medical staff, the others being the late Sir William Savory, Dr. Handfield Jones, Mr. William Adams, and Mr. George Lawson; the last two are happily still alive. The Hon. Reginald A. Capel, who made the presentation, referred to the history of the hospital, and pointed out how for thirty-eight years Dr. Cholmeley had worked for the hospital both as physician and on the committee of management, and how the present building with all its modern improvements was largely due to his exertions. He concluded by saying that a memoir to a man's worth during his life was, he thought, preferable to one erected after his death. Thanks were returned on behalf of Dr. Cholmeley, who has of late been in somewhat feeble health, by his brother, the Rev. C. H. Cholmeley.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. MARY'S HOSPITAL.

A CASE OF PLEURAL AND PERICARDIAL EFFUSION FOLLOWING ENTERIC FEVER AND ATTENDED WITH THE EXPECTORATION OF A FIBRINOUS CAST OF THE BRONCHUS; PARACENTESIS OF PLEURA AND PERICARDIUM.

(Under the care of Dr. CHEADLE.)

HOLSCHER reported 2000 fatal cases of typhoid fever in which post-mortem examination was held. Lung complications had proved fatal to the following extent: œdema of the lungs in 15 per cent.; bronchitis, 10 per cent.; lobular pneumonia, 8 per cent.; croupous pneumonia, 7 per cent.; and hæmorrhagic infarction of the lungs, 6 per cent. Plastic bronchitis was not met with, but in 15 of them tracheotomy had been performed, usually for perichondritis of the larynx. Landgraf considers that little importance can be attached to the marginal ulcers sometimes seen, especially about the epiglottis. Other deeper ulcerations, which occurred not only on the epiglottis but within the larynx, might be complicated with perichondritis, and were of grave import. The rarest lesions were ulcers which, from the time of their appearance, the infiltration of their bases, and the undermining of their edges, must be considered specific typhoidal lesions. The operation of paracentesis of the pericardium is but rarely required in cases of effusion into it. Dr. West collected a series of 79 cases in 1883 in which it had been performed, and of these 36 recovered. He considered that it was not only justifiable, but could be done without any great danger. It is not, however, an operation which is likely to be lightly undertaken, especially in rheumatic cases. Dr. Churton has reported a case of hæmorrhagic pericarditis, with serous effusion into the right pleura, in which he performed aspiration of the pericardium thirteen times and of the pleura seven times. The patient was a man aged forty-six, and at one time 46½ oz. were withdrawn. For the notes of this case we are indebted to Mr. Athelstan J. H. Saw, late house physician.

The patient, a man aged twenty-four, was admitted to St. Mary's Hospital on Oct. 3rd, 1894, complaining of shortness of breath and swelling of the abdomen and legs. His father died of phthisis. The history of the present illness is as follows. On May 12th, 1894, he was taken ill with enteric fever, and the temperature ranged between 100° to 103° F. There were typical stools and spots during the illness. The attack was not severe, and there was not an unusual amount of bronchitis. On June 26th the patient, having previously progressed satisfactorily, was attacked by pericarditis and pleurisy, after which the pulse was lost at the wrist. The patient's condition remained unsatisfactory, and at the end of July he went to Torquay. Whilst there he had œdema of the feet and legs, and eventually returned to London. On admission to hospital the patient appeared cyanosed. The veins in the neck, especially on the right side, were distended, also over the front of the chest. There was great œdema of the legs and of the chest wall and abdomen. He was unable to lie down in bed, especially on his right side. The pulse at the wrist was very small, hardly perceptible on the left side, but slightly larger on the right; it was easily compressed. The apex beat of the heart was neither seen nor felt. The cardiac dulness extended one finger's breadth to the right of the sternum, but could not be determined to the left and above owing to surrounding dulness. The sounds were heard very distinctly at the apex, but were louder at the base. The first sound was weak. He had an irritable cough, with but little expectoration. There was marked dyspnœa,

Digitized by Google

especially in the recumbent posture and when he was lying on the right side. The left side of the chest measured 19½ in. at the level of the nipple. The right side measured 17¾ in. The right lung was hyper-resonant over the whole of the right front and the back with good entry of air. The percussion note was absolutely dull over the whole of the left front and back. The entry of air was much impaired, especially at the base. The breathing was bronchial over the left front and the upper part of the left back. Vocal fremitus was diminished especially at the left base. The vocal resonance was slightly œgophonic at that base with marked whispering pectoriloquy over the front on that side. The abdomen was resonant. The liver reached four fingers' breadth below the costal margin. The specific gravity of the urine was 1026, acid; one-eighth albumen. A small quantity was passed of high colour. There were no casts. On Oct. 3rd an exploring needle was introduced into the left pleura and clear fluid removed, after which it was aspirated very slowly and with but slight pressure, 50 oz. of clear serous fluid being removed about 3.30 P.M. Immediately after the aspiration the patient started coughing incessantly, with expectoration of frothy, slightly blood-stained sputum. Inhalations of vapor coninæ and a hypodermic injection of one-sixth of a grain of acetate of morphia with one-fiftieth of a grain of sulphate of atropine gave no relief. He expectorated about a pint of this frothy serous fluid, which on examination was found to contain mucin and a large quantity of albumen. Notwithstanding the coughing he expressed himself as feeling better. About 10·45 P.M. he was seized with urgent dyspnœa, became pulseless, markedly cyanosed, his face being bathed in perspiration. His condition was extremely critical, and he was given hypodermically in quick succession five minims of liquor strychniæ, two minims of liquor atropiæ, twenty minims of ether, and a capsule of nitrite of amyl to inhale. Artificial respiration was performed and inhalations of oxygen were commenced as quickly as possible, from which he derived great relief. An hour and a half later (12.30 A.M., Oct. 4th), during a fit of coughing, he expectorated a large fibrinous cast of a bronchus with its ramifications, after which he was much easier. The inhalations of oxygen were kept up at intervals until 2.30 A.M. He passed a fair night, the breathing being easier. The cough was not so troublesome, though he still expectorated a frothy serous fluid. On the 6th the colour was better. The cough was not so troublesome. He had coughed up several (about half a dozen) blood casts of the bronchi, some of them branched, smaller than the fibrinous one alluded to above, much softer, and easily broken. The pulse was 126, small, irregular, slightly stronger than the day previous to the aspiration. The temperature, which was 101° on the night of the 5th, was 94·8° next morning. There was a Skodaic note over left front. The breathing was bronchial, and fine crepitations were heard during inspiration. Bruit d'airain was not obtained. The heart sounds were slightly more distinct. Note on percussion of the left back was still impaired. Air entered more freely. Crepitations were heard all over the left back during inspiration. The patient was ordered a mixture containing two grains of carbonate of ammonia, five minims of tincture of digitalis, and one ounce of chloroform water every four hours, also a hypodermic injection of five minims of liquor strychniæ every four hours. The patient improved somewhat and coughed up no more casts, but the fluid in the pleura gradually reaccumulated, and on Oct. 9th he was aspirated again, 50 oz. of clear fluid being withdrawn. After the aspiration he had a good deal of irritable cough. On the 17th the left pleura was drained by means of a Southey's tube, and 27 oz. of clear fluid drawn off. The patient bore this much better than the aspiration, and the subsequent cough was not nearly so troublesome. This was repeated on the 20th, when 48 oz. were removed. On the 24th the heart sounds still remained distant, and the area of cardiac dulness was much enlarged above the second space and a finger's breadth external to the right margin of the sternum and just external to the left nipple line. It was decided to aspirate the pericardium. The needle was introduced in the fifth space just internal to the left nipple line, and the bottle was only partially exhausted; 14 oz. of turbid serum were removed, quite different in character from the clear fluid obtained from the pleura, which became very thick towards the end of the aspiration. Microscopical examination of the fluid showed dead leucocytes and granular débris. After the aspiration the patient felt much relieved, and the dulness on percussion extended above to the fourth rib to the right margin of the sternum and just internal to the left nipple line. The heart sounds became a good deal more distinct and were accompanied by a to-and-fro crackling sound, which was not, however, due to air in the subcutaneous tissues, for pressure with the stethoscope made little or no difference. On Oct. 25th the left pleura was drained by Southey's tube, and 26 oz. of clear fluid removed without exciting any cough. On Nov. 8th the left pleura was aspirated by means of the bottle and vacuum; 35 oz. of clear fluid were removed, the last ounce being, however, blood-stained. An hour after the aspiration the patient had severe fits of coughing which became very distressing. The sputum was blood-stained, and of a frothy, serous nature, resembling that after the first tapping on Oct. 5th, but no fibrinous casts were expectorated. On Nov. 10th the pulse was distinctly better in force and volume. The apex beat of the heart could not be seen or felt. Dulness extended above to the third space, to the right to mid-sternum, and to the left half an inch external to the nipple line. At the apex the heart sounds were heard more distinctly. The first sound was somewhat sharp and followed by a second sound. There were adventitious sounds. The cough was still troublesome, and the expectoration was blood-stained. The note over the whole of the left front was good and resonant. A resonant note was obtained over the whole of the left back, but towards the base the note was not quite so good as on the right side. The entry of air was good except at the base. There were fine crepitations below a point midway between the spine and angle of the scapula during inspiration. The liver was one finger's breadth below the costal margin. On Nov. 15th the patient went home against advice. His general condition had improved very markedly, there being neither dyspnœa, distension of veins, nor œdema. Since his return he had been heard of several times through the medical man who was attending him. The last letter, dated March 1st, 1895, says:—"The patient remains in very much the same condition. Pulse quick, feeble, but regular. Heart sounds feeble and distant. No increase of pericardial dulness and no bruit. He has evidence of a slight amount of fluid at the left base, and since his discharge from the hospital has been aspirated twice, 36 oz. and 37 oz. respectively being obtained. He suffers from periodical attacks of very severe fits of coughing, when he becomes very cyanosed and veins much engorged. He expectorates small quantities of tenacious mucus, but has never expectorated any more fibrinous casts. He has marked signs of back pressure, his legs and genitals being very œdematous."

Description of cast.—The length of the main stem before subdivision was about 1½ in.; the diameter was about ¼ in. From the main stem there sprang about seven branches, each of which underwent still further subdivision and terminated in fine filaments. The colour was pure white. In consistence it was firm and tough. On section it appeared solid throughout and revealed a laminated structure. After placing in spirit it shrank considerably. Microscopically it showed a beautiful reticular arrangement, with some leucocytes entangled in the meshes. When stained by Weigert's method for staining fibrin the whole section took on the purple stain.

Remarks by Dr. CHEADLE *and* Mr. SAW.—We were at first disposed to think that the pleural and pericardial effusions might be due to the pressure of a mediastinal tumour. The subsequent history of the case negatives that view, we think, although it does not positively exclude it, for after the removal of the fluid we were never able to detect any evidence of a tumour. We also obtained a history of the case from the medical man who attended the patient at the onset of the illness, and there can be no doubt but that the patient had enteric fever complicated by pericarditis and pleurisy. There are two cases on record in which fibrinous bronchitis occurred either during or subsequently to typhoid fever, and in view of the invariable accompaniment of bronchitis in typhoid fever it is not surprising that casts of the bronchi should form, for no doubt one of the most potent disposing causes of fibrinous bronchitis is ordinary catarrhal bronchitis. But there may be another explanation of the occurrence of fibrinous bronchitis during typhoid fever. We know that ulceration of the upper part of the respiratory passage—viz., the larynx—is a by no means rare occurrence in typhoid fever. Only a few months previously to the admission of this case Dr. Cheadle had under his care a patient

Digitized by Google

suffering from typhoid fever, on whom tracheotomy had to be performed, owing to obstructive dyspnœa from this cause. Fagge[1] says: "Sometimes a thin pellicle of lymph has been found lining both the interior of the larynx and the epiglottis, and still more rarely a membranous layer resembling that of diphtheria." In a case under the care of Hoffman[2] tracheotomy was rendered necessary by the formation of a polypoid blood clot which hung down into the interior of the larynx. The cause of this ulceration, whether due to a specific poison or to the prolonged pyrexia, is uncertain. With this, however, we are not concerned. The fact remains that it is of fairly common occurrence, and if it occur in the larynx it is conceivable that it may also occur in the bronchi. Now von Gumoens[3] found in a necropsy on a case of fibrinous bronchitis that there was deep ulceration of the trachea and bronchi, which doubtless was the cause of the fibrinous exudation. In this way, therefore, we may explain the occurrence of fibrinous bronchitis during typhoid fever. That the cast had lain in the bronchi for some considerable time was, we think, manifest from its whiteness and toughness, differing entirely in its appearance from those coughed up the following day, which were softer, more yellow, and tinged with blood, resembling very closely "ante-mortem clot." There can be no doubt that ten hours previously to the expectoration of this cast there was no obstruction in the bronchi leading to the right lung, for there was a hyper-resonant note over the whole of this lung, with free entry of air; but it is very probable that it was lying in the bronchi of the left lung, which was collapsed, the auscultatory signs being concealed by the pleural effusion. Another explanation is possible, although we think not probable, as to the origin of this cast—namely, that after the aspiration of the left pleural cavity, the pressure being taken suddenly off the pulmonary vessels transudation of serum into the alveoli occurred, which was indicated, indeed, by the abundant serous expectoration; that this coagulated and became moulded in the bronchus; and that it was owing to the blocking of the bronchi that the urgent symptoms ensued about 11 P.M But had this been so we cannot suppose that the cast would have been as firm and tough as it was. Neither, assuming that it was formed in the left bronchus, do we think it would have caused such urgent symptoms; for the left lung, must have been lying collapsed for months from the pressure of the pleuritic fluid, and can have been of but little value for respiratory purposes; hence the blocking of its bronchus would make but little difference. On the other hand, had so large an obstruction occurred suddenly in the bronchus of the right lung we think the patient must have inevitably succumbed, for the left lung was collapsed, and there was also considerable pericardial effusion. What seems far more probable is that the fluid transuded after the aspiration and loosened the cast which was lying in the left bronchus, and that the violent coughing detached it, forcing it higher up the respiratory passages and so causing it to obstruct bronchi previously free. From the size of the cast the main stem probably occupied a primary division of the left main bronchus, probably that leading to the left lower lobe. Unfortunately, no clue as to the exact site occupied is afforded by the physical signs, for previously to the aspiration they were simply those of pericardial and pleural effusion with collapse of lung, and after the sudden onset of urgent symptoms prior to the expulsion of the cast our attention was directed to alleviating the patient's symptoms and so no precise and accurate examination of the lungs was made. The question arises, Why did the fluid in the pleural cavity reaccumulate so often? We think this was owing to the inability of the lung to expand, being perhaps bound down by adhesions, or so long collapsed that a return to the normal was impossible.

SIDCUP COTTAGE HOSPITAL.

TWO COMPLICATED CASES OF INGUINAL HERNIA IN WOMEN TREATED BY RADICAL CURE.

(Under the care of Dr. G. W. DAVIS.)

IN the first of these cases of inguinal hernia the presence of a second sac is of interest, although such a condition is not very uncommon, especially in the case of the male. It is probable that an old hernial sac became obliterated at the neck by inflammatory adhesion, and that it was afterwards pushed down by the descent of the hernia for which the operation was performed. The presence of the fluid in the first sac was either caused by extension of the inflammatory process from the second, in which the adherent omentum and intestine were found; or it may have been the site of a hydrocele. The second case is an example of a different arrangement of the two sacs, in which the second hernia had passed by the orifice of the first, which had become contracted in a way not infrequently seen in old-standing herniæ which are tending to become cured by contraction of the neck of the sac. Le Dran noted this tendency of empty hernial sacs, and found the entry of the sac contracted in several instances, especially where the patients had worn effective trusses.

CASE 1.—This case was remarkable, firstly, in having a distinct double sac, each of which contained fluid; secondly, in the embarrassment caused by the extremely tough adhesions; and, thirdly, in the absence of urgent symptoms in the face of the existence of strangulation. A widow aged forty-two years was seen by Dr. Davis for the first time for her hernia on June 3rd, 1893, at 10 P.M. She complained of having had a swelling in the right groin for ten years. This tumour had caused some discomfort during the whole of its existence and had never entirely disappeared; it had given rise to more pain for the last three years, during which time she had followed the calling of a laundress. Especially had she suffered from the swelling for the previous three days, and each day's suffering had been more acute than that of the one preceding. The swelling was egg-shaped and of the capacity of about one and a half ounces. It was very tense and both tender and painful, but not markedly so. There had been occasional vomiting during the day, but not feculent. The bowels had acted slightly in the morning. No food had been taken during the day. Efforts at reduction, both by taxis and ice, having been already made, it was decided to admit her at once into the Sidcup Cottage Hospital, which was accordingly done at 11 P.M. on June 3rd. Dr. Burrell gave chloroform, and Dr. Lionel Burrell assisted at the operation. The usual incision having been made and the superficial tissues incised, a thin-walled sac tense with fluid bulged forward; this, being nicked and freely opened, disclosed a second sac of a bluish-black hue; in pinching up this second sac in order to ascertain its thickness its distension caused it to burst and the fluid which had given rise to its colour to escape. The sac contained a portion of gut just protruding through the ring and firmly attached to the sac by old fibrous adhesions on all sides except internally, where it was adherent to a nodulated mass of omentum, and this omentum in its turn was attached to the sac wall. Some considerable time having been spent in endeavouring to break down the adhesions between the gut and sac without much result, the adhesions between the gut and omentum were broken down, so that the fingers could travel with difficulty along the canal to the internal ring, at which was felt a tightly constricting narrow orifice; this being cut in the usual manner, the omentum was dealt with by first drawing it further out and then ligaturing it in two parts with chromicised gut, removing the part above the ligature and returning the stump into the abdomen. The adhesions on the gut were now separated from the sac, and the gut and adhesions returned into the abdomen. The canal being examined and found to be clear, the sac was ligatured with silk and removed, the stump being returned. The wound, after being irrigated with a 1 in 2000 perchloride of mercury solution and dusted with iodoform, was brought into accurate apposition by means of silkworm gut sutures; the dressing was of double cyanide gauze and pine-wool pad. A drainage-tube was inserted and removed in twenty-four hours. The patient made an uneventful recovery, with the exception of having much distressing retching and vomiting of clear, olive-green, bilious matter. A light truss was procured, and the patient left the hospital. In November, 1894, there was a very slight impulse during severe coughing.

CASE 2.—This case was remarkable from the complicated nature and number of the protruding masses. These were, firstly, an elongated mass of fat, perhaps subperitoneal; secondly, an encapsuled mass of omentum; and, thirdly, a sac which was empty and had so constricted a neck as to resemble the sac of a water-bottle hydrocele, but had apparently no intimate connexion with the round ligament. A young woman aged twenty-six had suffered for three years from a swelling in the left groin. During the night and before

Digitized by Google

rising she was not conscious of there being anything wrong, but during the day, or in the performance of any work, the swelling appeared and became a continuous source of discomfort and occasionally of pain. On examination of the swelling on Oct. 7th, 1894, it appeared to consist of two parts—viz., one irreducible, but defined with difficulty, and the other not reducible in the ordinary sense, but rather insensibly disappearing during the exercise of the pressure incidental to examination. These conditions were not easy to appreciate, and from the first impression a truss was ordered, but the endeavour to wear it caused great pain and even retching; it was therefore at once discarded and an operation advised. A further examination in consultation with Mr. F. Shapley having confirmed this opinion, the patient was admitted on Oct. 16th into the Sidcup Cottage Hospital. The operation had, however, to be postponed on account of menstruation. For a few days previous to the operation she was kept a good deal in bed and given a dose of Æsculap every morning. Dr. Crombie gave chloroform, and Mr. C. de S. Hoar assisted. The patient commenced to retch at once, but no appreciable impulse was communicated to the tumours. An incision three inches long was made, crossing the external ring and extending in the direction of the canal. A soft mass of fat the size of a walnut was almost immediately found at the anterior part of the wound; on the fat of the superficial fascia having been removed from this mass, it was found to be encapsuled and to have a pedicle passing through the external ring. The tough capsule enclosing the mass having been opened and stripped from it, a mass of nodulated omentum was disclosed; the pedicle, being drawn up, was ligatured with catgut, cut off with scissors, and allowed to retire through the canal. A second long and narrow mass of fat, non-encapsuled, was found above the first and was taken to be some of the subperitoneal fat; its pedicle was ligatured as was that of the other mass, and the stump was returned. Further dissection disclosed an empty, tough, fibrous sac capable of holding about one and a half ounces of fluid; this after careful inspection was opened and found to be continuous with the peritoneum lining the canal, along which the little finger could be inserted with difficulty. The pedicle of this sac was tied with a threefold ligature of catgut, the sac being removed and the stump returned to the inner ring. Finally the pedicle of the fibrous covering of the omental mass was ligatured and removed, and the stump remained within the external ring. The wound surfaces, having been cleared of a gland and some redundant pieces of fat, were covered with iodoform, and the two surfaces brought into accurate apposition with four deep sutures of silkworm gut and five superficial sutures of horsehair. The dressing was of double cyanide gauze wrung out of a 1 in 20 carbolic acid solution and covered with a pine-wool pad. A great deal of retching followed the operation and continued throughout the night, and was the next day associated with green vomit. At 1.30 P.M. the patient fell asleep, the vomiting having ceased; it, however, recommenced and was again very distressing throughout the night. The temperature was not high (99·2° F.), the pulse was 98, and there was no tenderness of the abdomen or tympanites. A hypodermic injection of half a grain of morphia relieved the vomiting. The tongue was very much furred. On Nov. 4th the patient appeared to be going on quite well. The temperature was 100 on Oct. 26th, but fell to 99·4° on the 27th, was the same on the 28th, and from the 29th to Nov. 4th remained normal, the bowels being opened daily. On Nov. 5th, exactly fourteen days after the operation, the patient, who had been up for six days, was seized with a rigor accompanied by pains in the back and head, and the temperature reached 103°. The wound was a little tender and there seemed to be some infiltration in the underlying tissues, but nothing sufficient to justify one in opening the wound. She was therefore sponged and given salicylate of soda. On Nov. 6th the temperature was 100°, on the 7th 99·6°, and on the 8th it fell to normal and did not rise again subsequently. During the night a quantity of pus and serous-looking fluid escaped into the dressings. On the 9th a drainage-tube was inserted through the wound in its entire length. On the 25th, all efforts to close the sinus through which the drainage-tube had been inserted having failed, cocaine was injected and the sinus was opened upon a director. The after-progress was extremely tedious. The wound was packed each day with iodoform gauze, but after healing to about half its extent it appeared to become chronic and to remain so in spite of applications of sulphate of copper, of nitrate of silver, of chloride of zinc, &c. Finally, the application of lead paper as a dressing seemed to hasten the process, and the application of a leaden shield with a depression, which was made for the purpose, fitting into the wound, certainly did some good. On Dec. 26th the wound had healed.

Remark by Dr. DAVIS.—A remark is called for on account of the omission in each case of any attempt to close the canal by suture. In Case 1 the length of time already expended in breaking down adhesions led me to omit this precaution. In Case 2 the canal did not appear abnormally patent, and the sutures were omitted by design.

Medical Societies.

EDINBURGH OBSTETRICAL SOCIETY.

The Condition of Midwives in Scotland.

A MEETING of this society was held on July 10th, Dr. A. H. FREELAND BARBOUR President, being in the chair.

Professors A. Martin (Berlin), A J. C. Skene (New York), and Pinard (Paris) were elected honorary Fellows.

Photographs of a Fœtus sent by Dr. Farquharson (Newcastle) were exhibited, showing a case of anencephaly, retroflexion of the spinal column, cleft palate, and hare-lip. There was a distinct family history of spinal and brain disease.

Dr. D. BERRY HART opened the discussion on the Condition of Midwives in Scotland, with special reference to the question of registration; Should midwives be registered in Scotland? Lord Balfour's Bill had passed the second reading in the House of Lords, but the Dissolution had postponed its progress. He had little doubt it would be reintroduced, and it might be considered in the meantime. It only applied to England, but if passed it would soon be extended to Scotland and Ireland. It was named the Act for the Compulsory Registration of Midwives. Lord Balfour had shown an undoubted evil: the returns reported 800,000 to 900,000 births yearly in England, and one-half of these were attended by midwives only, and these midwives were wholly or almost wholly untrained. This was the only European country where midwives were not registered. It was estimated that there were 10 000 to 15 000 midwives in England and Wales, and uneducated. In the Bill as introduced the midwife was defined as one who should only attend natural labour; but in the amended Bill no definition was given. He then explained some portions of the Bill. The Bill had defects, and the question attempted to be solved was difficult, and he thought the best plan was to obtain a satisfactory compromise. We must admit that 500 000 births were attended by midwives, in many cases ignorant; and yet this Bill provided at a reduced fee for the registration of those now practising, even if ignorant. Registration does not mean education. Then this Bill does not make any provision for the education of the candidates. In this country there is not sufficient hospital accommodation for the purpose. As a compromise, he advised a Bill for the registration of midwifery nurses.

Dr. BUIST (Dundee) viewed the Bill with favour, and stated that this was the general opinion of the profession in Dundee. A large part of the population was poor and unable to pay the fee of a medical man, and the alternative was that the medical man should work for 10*s.* 6*d.* or have the case attended by a midwife. His experience was to trust the midwives if supervised. He gave instances where he had been sent for in complications and found the previous treatment satisfactory. At present the midwives were under no control at all, whereas if registered they could be made liable for malpraxis and their sphere of practice limited. He had known one to give quinine, another to give opium pills to a patient with albuminuria, and another to prescribe ergot during pregnancy. If such women had been registered their certificates could have been dealt with. The question of midwives was entirely one of cost, affecting those people who were too poor to pay for medical attendance. Matters could be left as at present, or these might be dealt with by the Poor-law, but the feeling associated with this was against it. Another suggestion was a municipal or dispensary system, the

Digitized by Google

latter supplying the need in Edinburgh. Another plan was the insurance system, but these people do not at present even insure against sickness; or, lastly, cheap midwifery fees. The aim should be to protect the poor.

Dr. CONNEL (Peebles) preferred registered qualified nurses to registered midwives. Thirty years ago the usual practice in his district was to send for some woman; now they send for a medical man, but they do not all pay. Medical education has now permeated the general public, and accordingly they trust medical practitioners and see that the uneducated person is not to be trusted. To register these uneducated women would be a retrograde step; if they were only to attend natural labour, who was to define it? Perhaps the State should take care that the woman was insured against labour—this was surely a matter of public health.

Dr. MACVIE (Berwickshire) stated that midwives were unknown in his district. He considered it was all a question of cost. If a man could not pay the rent of a good house, should a Bill be brought in to allow him to occupy an unhealthy dwelling? All improvement of medical education was for the benefit of the public, and education was becoming more costly. The difficulty of the position was really the matter of poverty, and to make provision for the improvident; the provident get the medical man.

Other speakers agreed that if there was registration there should be some medical qualification and education for it. One stated that he had always found trained nurses acting satisfactorily in conjunction with medical men, and that a country practitioner's life would be intolerable if there were no midwives.

Professor SIMPSON felt strongly that the creation of this special group of women as advanced was a dangerous experiment. The worst feature was that women imperfectly educated were put in charge of a case that required the training of a full medical curriculum. The training given to women at the Maternity Hospital extending over three months was useful and satisfactory. These might be registered.

Sir WILLIAM TURNER stated that from his position as chairman of the committee appointed by the General Medical Council to inquire into this Bill, he had found it necessary to consider this subject. The amended Bill, of which he had only received a copy at this meeting, was very different from the Bill that was under the consideration of the Council. The definition of midwife was entirely dropped out. This definition was a limitation—to limit its scope to women who attended natural labour without a medical man. The amended Bill allowed women to attend all cases, natural or unnatural. The objection to the term "midwifery nurse" was that it placed the woman on the same status as medical or surgical nurses. The latter only acted under the direction of a medical practitioner, whereas the midwife is to attend cases by herself and take an initiative in these matters; and thus there would be a new definition for the term nurse. There were other alterations in the amended Bill; the suggestions of the General Medical Council had not been incorporated by the Government. One thing should be prevented, and that was to allow this register to become loaded with women inefficiently qualified. The Council had had experience of this trouble in the registration of dentists, some of whom seemed to be placed on the register whose sole claim was that on one occasion they may have drawn a tooth. Any woman could be put on this register, but the Council recommended that they should present certificates from a person of authority in the district. This had been ignored, and action should be taken in this matter. He drew attention to the constitution of the Midwives Board; as amended, three other persons were added. It was composed of fifteen members, and one at least must be a woman. The Incorporated Midwives' Institute was to be represented—and what was it? He found it to consist of a body of philanthropic ladies, who had applied to the Board of Trade and received a charter, so that they had now a certain legal status. They were excellent ladies, but what special claim had they to form part of a board composed of representative physicians &c.? In Scotland the Bill did not seem to be required; in England a great want was met by it. There was a great amount of malpraxis; the people needed midwives, but surely these women should be educated. He must support any measure to register women who were properly qualified, and that was by proper education. The General Medical Council inserted words to show that the women should have a proper training; they could not be examined unless they had a previous education, and in England provision must be made for their education. The General Medical Council does not countenance any examination which does not show proper and *bonâ fide* education. Examination must precede registration; but the registration must apply to the new woman, not the old midwife. After the passing of the Act the Council would insist on the women having a knowledge of midwifery. The main difficulty was because the limitation was left out of the amended Bill, and it also contained some minor objections.

Dr. BATTY TUKE considered that registration was not required in Scotland. They had now to face an entirely new position since the definition had been left out of the Bill. A midwife would now become a fully qualified practitioner. The Bill should be resisted as far as possible in the absence of the definition of the term "midwife."

Dr. NORMAN WALKER stated that this proposal would only affect the poor, and was entirely due to the expense of attendance. Newcastle had solved the difficulty by its system of dispensaries with a staff of medical men and midwifery nurses, who called in the medical attendant if necessary. Abroad registration of midwives was in force. He gave the experience of two German medical men. One had been called to a patient and found that the midwife had injected pure carbolic acid into the vagina; he was bound to report this to the authority, and it resulted in the loss of his practice. Another medical man in Hamburg found he was succeeding for two years, but in one month all his midwifery practice disappeared. On investigating he discovered the fact that new practitioners had come who were giving a percentage to the midwives for all cases sent them. In a certain district of England it was known that the medical men paid commission to the midwives when sent for to their cases. He hoped that if any Bill passed a thorough system of education would be demanded, and that the midwives would act under the supervision of some medical man.

Mr. THATCHER, from his experience as a teacher of nurses for twenty years, considered midwives absolutely essential in Scotland for populous and large colliery districts. To have properly qualified midwives is a protection to women in their confinement. He considered a three months' course rather short, it could be made longer with advantage.

Dr. BARBOUR, in referring to the practical conclusion of the discussion, remarked that in Scotland there was not any great need at present for this Bill, but that it should be watched very closely, as if it were passed for England it would soon be extended to Scotland. In doing so attention should be given specially to the definition of midwife, to the provision for their education, and to the composition of the Midwives Board, where it was absurd that members of the Institute should be placed on the same level as the representatives of the Royal Colleges of Physicians and Surgeons.

After the discussion a large number of Fellows and friends dined together in the Waterloo Hotel. The occasion was a special one, Professor Simpson being made the guest of the evening as the twenty-fifth anniversary of his appointment to the Chair of Midwifery had occurred a few days previously. Dr. Barbour presided. Dr. James Ritchie proposed the toast of the guest of the evening, which was enthusiastically received by the company. Professor Simpson, in reply, gave some pleasant reminiscences of his early professional life and his association with Sir James Simpson, and made special reference to his different assistants. The toast of the University was appropriately replied to by Sir Wm. Turner.

PRESENTATIONS.—Dr. Samuel Grose, of Westbourne, Melksham, Wilts, on the occasion of his leaving that town, where he had been in practice for twenty-two years and upwards, has been presented with a handsome silver-clasped wallet and a purse of money, on which is inscribed: "This purse, with 50 guineas, was presented to S. Grose, Esq., M.D., by friends and patients on his departure from Melksham."—Mr. Alexander Gordon, L.R.C.P. Irel., L.R.C.S. Edin., of Rathmines-road, Dublin, has been the recipient of an illuminated address and a gold medallion, highly embellished and bearing a suitable inscription, from the president, committee, and members of the Dublin Hebrew Society for Visiting the Sick, in recognition of the services he has rendered for many years to the members as medical officer to the society.—Dr. George W. H. Tawse, house surgeon to the Whitehaven Infirmary, has been presented by the members of the Whitehaven Police St. John Ambulance Class, to whom he has given a course of lectures on "first aid," with a handsome dressing-case and meerschaum cigar-holder.

Reviews and Notices of Books.

The Value of Electrical Treatment. By JULIUS ALTHAUS, M.D., M.R.C.P., M.R.I., Consulting Physician to the Hospital for Epilepsy and Paralysis, Regent's-park. London: Longmans & Co. 1895.

THOSE who remember the third edition (1873) of Dr. Althaus' work on Medical Electricity may possibly be disappointed in the present volume. How far there are grounds for such disappointment is not quite easy to determine. Compared with its predecessor this book must be judged rather by its more limited scope than by its less imposing dimensions. "Having been in intimate touch with the subject through a long professional life," the author now submits "once more" his "views on the uses and limits of usefulness of electricity in medicine." He deals with the three currents ordinarily used in the treatment of disease, giving special attention to the constant galvanic current, which he considers "by far the most important form of electricity for medical purposes" (p. 4). The views and methods advocated by the author in former works have in some instances undergone modification, and there is the important addition that, with improvements in electrical measurement, current strength (intensity) can now be accurately stated in milliampères. Density, an important factor in dosage, is also in most instances definitely expressed by giving the superficial area of the electrodes used. Would it not be desirable to adopt throughout the method originally suggested by C. W. Muller, and explained in this book, of giving this information in the form of a fraction where the numerator is the strength of the current in milliampères and the denominator the number of square centimetres of surface of the electrode? Thus $\frac{10}{30}$ would express the fact, not only that the intensity of the current is ten milliampères, but that its density is one-third of a milliampère to the square centimetre of electrode surface. Regarded as an exposition of the individual views of the author on the question of electrical treatment, this volume of 100 pages has a distinct interest and a unique value. Were it to be regarded as an attempt to bring the work of 1873 into line with present science it could not be pronounced a success. It is true that a few pages are devoted to a consideration of ohms and volts, and ampères and coulombs, with a short description of the faradimeter and plates of Lewandowski's rheostat and Edelmann's galvanometer; but contemporary and recent work, notably that of the French and American schools, is almost completely ignored. Thus D'Arsonval's investigations as to the effects on nutrition of different forms of electrical energy—including sinusoidal currents, as well as currents of great frequency and high potential—are not even alluded to. Apostoli's treatment of uterine fibroids is dismissed with the remark that space is too limited to consider it. "Metallic electrolysis" is not mentioned; nor is the opportunity taken of formally withdrawing the opinion expressed in the volume of 1873 that the idea "that electricity may serve to introduce drugs into the system is untenable" (p. 708). For the latter sentence something like the following might now have been substituted: "The transference of drugs through the uninjured skin by means of the directional influence of the constant current has been experimentally demonstrated by physicists and is now a recognised practice in medicine." The suggestion (p. 708) that Fabré-Palaprat's proposition was due to "ecstatic spasms" might at the same time have been gracefully withdrawn, and this is scarcely atoned for by the slight reference to cataphoric medication at p. 63 of the present book. The author might also have availed himself of this opportunity to modify the commencing sentence of the former work, which is this: "In the present state of physical science it is generally admitted that all substances contain a very subtle and imponderable fluid called natural electricity ....." For this it would have been fairly correct now to write as follows: "In the present state of physical science few things are more certain than that electricity is not a fluid." Such points are adverted to simply to warn the reader that he must not expect in the present volume an "up-to-date" book covering the whole ground of medical electricity, such as was Dr. Althaus' work of 1873. Passing from what the book is *not* to what it is, the author believes that "Pflüger's researches on electrotonus supply the key to the large majority of the therapeutic applications of the constant current" (p. 18). Thus the anode will prove curative in suitable cases of hyperæsthesia, neuralgia, tinnitus aurium, muscular spasms, contractions, &c. The cathode will "find its appropriate sphere of action where excitability of a nerve or neurone requires to be increased, that is in paralysis and anæsthesia." The existence of electrotonic modifications of excitability under the influence of electric currents is of course beyond doubt. But, admitting this, and even admitting that neuralgic pain points to an increase of excitability, and paralysis to a diminution thereof, there still remain the old and destructive arguments against accepting the electrotonic theory as a basis of electrotherapeutics. These cannot be entered into here. Judged by the rules of procedure laid down in this book, the induction of anelectrotonus and catelectrotonus would seem to be as easy and as certain as to induce contraction in the long flexors of the fingers. Thus regarding, as Dr. Althaus does, shaking palsy as a "neurosis of the Rolandic convolutions, and as the symptoms are more those of debility than of irritation" (p. 44), the procedure at once becomes obvious—simply to induce catelectrotonus "in the motor portions of the cortex," and for this purpose the use of one milliampère of current through an anode of 130 square centimetres seems to be recommended—i.e., a current density of $\frac{1}{130}$ of a milliampère to the square centimetre. It seems almost time to enter a protest against the retention of the term "catalytic action." That uniform direct current known as the galvanic may be stated to have certain physical and physiological properties. These can be discussed each under its own name—as proved, probable, possible, or impossible; none of them need be lumped together under a term whose only claim to usefulness seems to be that it has no definite meaning of its own. Turning to the consideration of faradaism, its stimulating or excitant effects only are mentioned. Reference might have been expected to the well-established sedative and "numbing" effect of the fine wire coil. In discussing Franklinism (p. 4) it would almost appear that there exists in the author's mind some confusion between ordinary disruptive discharge (sparks) and Morton's "static induced currents." It is the former that Dr. W. J. Morton of New York recommends in the treatment of locomotor ataxy but it is the latter (obtained by adding condensers to the static machine and other special disposition of the apparatus) that Dr. Morton first described, and with which his name ought therefore to be associated. Amongst the diseases dealt with is "spinal debility," and the author considers that "many persons, especially young women," suffer from it. Here electrical dosage is not entered into with the author's usual exactitude, but it is satisfactory to learn that the "constant current applied to the spine, both horizontally and longitudinally, had an excellent effect." Another of the diseases considered (p. 33) is "failure of brain power," which "may be defined as paresis or want of action, and as undue excitability or over-action of the different functions of the brain" (p. 34). This condition, the author states, "is often called neurasthenia." Possibly some readers will still prefer to regard both one and the other of these terms as "question-begging epithets," and to adopt the word "neurasthenia" merely as a term signifying a clinical entity of a pathogenic origin as yet unproved,

Digitized by Google

but displaying itself by certain well-marked preponderating symptoms or "stigmata." The cerebral condition here described as "failure of brain power" is one of those stigmata. One very striking and instructive feature of the book is the comparatively feeble strength of current recommended. For the brain ½ to 2 milliampères with an effective electrode of 16 to 130 square centimetres, and for the spine 2 to 10 milliampères with an electrode surface of 40 to 130 square centimetres, give a fair idea of the intensities and densities used. There will be many who differ from this, but those who clamour for a treatment more heroic must do so with eyes open to the formidable power of the energy they employ, and never forgetting the old Hippocratean precept, "Imprimis non nocere."

Dictionary of National Biography. Edited by SIDNEY LEE. Vol. XLIII. Owens — Passelewe. London: Smith, Elder, and Co. 1895

THE proportion of medical biographies in this volume is relatively considerable, including those of three presidents of the Royal College of Physicians of London and one president of the Royal College of Surgeons of England. Sir William Paddy was born in London in 1554, graduated as M.D. at Leyden in 1589, and became a Fellow of the Royal College of Physicians of London in 1591. He was elected a Censor in 1595 and 1597, and was four times President—in 1609, 1610, 1611, and 1618. Having been appointed physician to James I. soon after that monarch's accession, he was knighted in 1603, and was in attendance during the King's last illness in 1625. Sir William died in 1634; his tomb is in St. John's College, Oxford. Another Court physician contemporary with the preceding was Richard Palmer, who was elected a Fellow of the Royal College of Physicians of London in 1597; he was nine times Censor between 1599 and 1619, and was President in 1620. He also possessed the degree of M.D., but the name of the university is not recorded; he died in 1625. Dr. Palmer was one of the physicians who attended Prince Henry, eldest son of James I., during his fatal illness in 1612. John Ayrton Paris was born at Cambridge in 1785, studied medicine there and in Edinburgh, and graduated as M.D. Cantab. in 1813. He was elected a Fellow of the Royal College of Physicians of London in 1814, and from 1819 to 1826 lectured there on Materia Medica. He was also Censor for several years, Harveian orator in 1843, and President for twelve years, commencing from 1844. He died in 1856. He had a large practice, and his published works passed through many editions; the principal of them are his "Pharmacologia," "Medical Jurisprudence," "Treatise on Diet," and "Life of Sir Humphrey Davy." Richard Partridge was born in 1805 at Ross, in Herefordshire, studied medicine in Birmingham and at St. Bartholomew's Hospital, and qualified as M.R.C.S. in 1827. On the foundation of the medical faculty in King's College, London, in 1831, he was appointed the first demonstrator of anatomy, and held the position till he became, in 1836, Professor of Descriptive and Surgical Anatomy. In 1837 he was elected a Fellow of the Royal Society, and in 1840 he was appointed surgeon to King's College Hospital, then newly established, and retained this office till 1870. He was made a Fellow of the Royal College of Surgeons of England when the Fellowship was instituted by the Charter of 1843, and was elected Hunterian orator in 1865 and President in 1866. Although a good lecturer and skilled in drawing, he published nothing beyond contributions to the "Cyclopædia of Anatomy and Physiology" and to the Transactions of various societies. A far more distinguished representative of medical science than any of those just mentioned was Edmund Alexander Parkes, who was born in 1819, studied medicine at University College, and graduated as M.B. of London University in 1841. From 1842 to 1845 he served as a military surgeon in Madras and Moulmein, retired from the army in 1845, graduated M.D. at the University of London in 1846, and in 1847 published a work "On Asiatic and Algide Cholera," which was chiefly written in India, where he had witnessed two epidemics. In 1849 he was elected Professor of Clinical Medicine at University College and Physician to University College Hospital. During the Crimean War the hospital accommodation at Scutari was found to be insufficient, and the Government having resolved to provide an additional civilian hospital, Parkes was sent to Turkey to select a site for the building and to undertake the organisation and general management, duties which occupied him till 1856, when hostilities terminated. In 1860 an Army Medical School was established at Fort Pitt, Chatham, and Parkes accepted the chair of hygiene, thereby bringing to a close his connexion with University College. In 1863 the school was transferred to the Royal Victoria Hospital, Netley, and in the following year he published his celebrated "Manual of Practical Hygiene." Several other works were written by him, as well as numerous important contributions to periodical literature. He was elected F.R.S. in 1861. He died in 1876, leaving an imperishable name as the principal founder of the science of modern hygiene and furnishing a remarkable object lesson of the ingratitude of Governments, for his transcendent merits were almost entirely ignored. Thomas Heazle Parke was born in county Roscommon in 1857, studied medicine in Dublin, qualified there in 1878, and entered the medical department of the army in 1881. Next year he saw service in the Egyptian campaign, and subsequently took part in the expedition sent to rescue General Gordon. In February, 1887, he accompanied, as a volunteer, the expedition into the Congo forest organised by Mr. H. M. Stanley for the relief of the German traveller, Emin Pasha. Emin could not be persuaded to leave Africa; but the expedition was otherwise completely successful, and Parke returned to England in May, 1890. He was heartily welcomed by the medical profession there, and the biographer does not omit to mention his enthusiastic reception at the office of THE LANCET. Mr. Stanley freely acknowledged how invaluable was the aid rendered by Parke to the expedition. His military service was now resumed with the 2nd Lifeguards and at Netley Hospital; but his health was permanently injured, and he died in 1893. Of the other medical biographies included in this volume, the most notable is that of Sir George Edward Paget, Regius Professor of Physic at the University of Cambridge from 1872 to 1892. Denis Papin was born at Blois in 1647, and studied medicine at the University of Angers, taking his degree in 1669. He devoted himself to natural philosophy and mechanics, came to London in 1675, and was elected Fellow of the Royal Society in 1680. His principal invention was the digester, an apparatus for boiling food under pressure, which was shown to the Royal Society in 1679, and which is in use at this day.

Thomas Parr—known as "Old Parr"—who died in 1635 at the alleged age of 152 years, was not equal in longevity to his contemporary, Henry Jenkins, a Yorkshireman, who is said to have seen 169 years. These, however, were pre-registration days, and verification of the date of birth was not easy in the case of centenarians in humble life. The opening memoir of the volume is that of John Owens, founder of Owens College, Manchester; the longest, extending over almost twenty pages, is that of Charles Stewart Parnell, the Irish political leader.

St. Bartholomew's Hospital Reports. Edited by SAMUEL WEST, M.D., and W. J. WALSHAM, F.R.C.S. Vol. XXX. London: Smith, Elder and Co. 1894.

THE contributions from members of the staff and others, which occupy the first part of the contents of the volume

Digitized by Google

chiefly consist of notes on cases which have been under treatment in the wards or out-patient department of the hospital, rather than of contributions of higher importance, but some of them are of unusual interest. Dr. Samuel Gee contributes a case of Aneurysm of the Ascending Part of the Arch of the Aorta, taking the Natural Position of the Heart. Dr. W. P. Herringham writes on the somewhat rare disease Primary Cancer of the Pancreas, and gives an abstract of seventeen cases which had been under observation at the hospital; he also analyses forty others collected from various sources. Dr. A. E. Garrod contributes a paper on the Association of Cardiac Malformations with other Congenital Defects. Dr. Lauder Brunton gives a note on Hydroxylamine Hydrochlorate as a Substitute for Nitrite of Amyl or Nitro-glycerine. Dr. H. Lewis Jones writes on the Treatment of Nævus by Electrolysis. Amongst the surgical contributions the most remarkable is the account of a case by Mr. Thomas Smith in which the superficial femoral, the deep femoral, and the popliteal arteries, with their corresponding veins, were tied in the course of an operation without damage to the vitality of the limb. Mr. H. T. Butlin gives an account of his experience of a Second Year's Surgery at St. Bartholomew's Hospital, chiefly with regard to the treatment of wounds by an antiseptic method. The results are better than they were during the previous year, but do not attain the high standard expected at the present day; for instance, in operations for varicose veins suppuration occurred in one out of five cases; for radical cure of hernia in nine out of twenty-seven; and in amputations of the breast in two out of fifteen. Mr. Walsham writes on Purulent Catarrh of the Accessory Nasal Sinuses. Other contributions are as follows: Mr. Richard Gill, Notes on Chloroform Anæsthesia; Dr. C. Hubert Roberts, the History and Present Position of Symphysiotomy; Mr. E. Percy Paton, a Case of Peri-cæcal Suppuration followed by interesting Cerebral Symptoms; Mr. R. Cozens Bailey, the Treatment of Senile Gangrene; Mr. W. McAdam Eccles, the Great Omentum, Notes on its Development &c.; Mr. E. Willett, a Case of Lymphangioma of the Skin; the Rev. G. Henslow, the Dietetic Value of Food-stuffs prepared by Plants; Dr. H. M. Bowman, a Case of Congenital Absence of both Pectoral Muscles; Mr. J. J. Macan, the History of Diphtheritic Paralysis; Dr. J. A. Hayward, the Diagnosis of Diphtheria; Dr. James Adams, Diphtheria, Immunity of Puerperal Women from its Infection; Diagnostic Value of the Patellar Reflex; Dr. Harry Campbell on the Gradations of Health and Disease; Mr. Thomas J. Horder, the Life and Works of Percivall Pott, being the Wix Prize Essay for the year 1894; Dr. W. J. Horne, Notes on a Case of Fugitive Œdema of Obscure Origin ending fatally; Dr. G. C. Garratt, a Case of General Tuberculosis, with Cortical Tubercular Meningitis producing Localising Cerebral Symptoms; Mr. D. H. Goodsall, Three Cases of Right Iliac Colotomy for Intestinal Obstruction; Dr. S. West, Blood Casts in Phthisis; and Mr. C. A. Morton, a Case of Aural Pyæmia (fatal).

The second part of the book contains: (1) an account of the proceedings of the Abernethian Society for the Session 1893–94; and (2) a list of the specimens added to the museum during the year ending Sept. 30th, 1894, described by Mr. Edgar Willett, amongst which there are many of considerable interest and rarity.

The third part really contains the Hospital Reports—the statistical tables of the patients under treatment in the wards during 1893 by the medical registrars, Drs. Ormerod and Herringham, and the surgical registrar, Mr. James Berry. The medical cases under treatment during the year were 2515, and of these 511 died. The surgical cases were 3986 cured or relieved, and 233 died. Whilst members of the profession will be fully appreciative of the appendices to the surgical tables, in which some of the most interesting cases are summarised, they would be thankful, we think, if sufficient information was given in them to make the abstract of them available for useful reference.

LIBRARY TABLE.

Hygiene, with Anatomy and Physiology. By JOSEPH F. EDWARDS, A.M., M.D., Fellow of the College of Physicians of Philadelphia. New York: Edward P. Slevin. 1895.—The author states expressly (p. 19) that this book is not written for "medical students," and on the title-page it is described as being intended for schools and for general reading. The style is often colloquial and the various arguments are sometimes illustrated by far-fetched comparisons and sensational engravings. For instance, the evils attendant on the escape of sewer air from faulty drain-pipes in the basement of a house are represented by large serpents issuing from the crevices of the pipes and thrusting their formidable heads into the sitting-rooms and bedrooms. A strict observance of the laws of health is what the author seeks to inculcate, mainly through the medium of quaint analogies. Some of these may not be very appropriate, but all the practical recommendations as to personal hygiene are excellent.

The Theory of Physical Education in Elementary Schools. By THOMAS CHESTERTON, Organising Teacher of Physical Education to the London School Board. London and Aldershot: Gale and Polden, Limited. 1895.—About four years ago the author of the present volume published a "Manual of Drill and Physical Exercises," which has passed through several editions, and he now enters on fresh ground with a treatise on the theory of the subject, intended mainly for the use of teachers in elementary schools. Its principal object, in fact, is to prepare candidates for the examinations held by the London School Board and other educational bodies in order to test the proficiency of school teachers in the theory of physical education. The first eighty pages contain an outline of human anatomy and physiology sufficiently full and accurate except that on p 71 "the highest temperature of the body" is given as 40° C., without any mention of the co-existing ill-health. The remaining sections are on the utility of dumb-bells and music as adjuncts in the physical training of children, on the distinction between games and formal exercises, on spinal curvature, &c. Mr. Charles Roberts, F.R.C.S., contributes a few pages on singing and declaiming as physical exercises, and numerous examination papers are subjoined. The book is well adapted to the end in view.

The Phonographic Record of Clinical Teaching and Medical Science. London: Sir I. Pitman and Sons.—The June issue of this excellently lithographed magazine contains a clinical lecture by Professor T. Grainger Stewart on a Case of Renal Disease, and a paper on Neurasthenic Asthenopia by Mr. Edward Nettleship. A short note from the clinic of Dr. Judson Bury on Functional Aphasia is reported by Mr. Leonard Sessions, and Dr. W. R Gowers contributes an interesting and important paper on Problems in Practical Diagnosis. The July number, which is a double one, contains several papers of interest to both student and practitioner. Dr. Gowers continues his Problems in Practical Diagnosis.

The Treatment and Education of Mentally Feeble Children. By FLETCHER BEACH, M B.Lond.—In a small book of thirty-two pages Dr. Fletcher Beach summarises his observations resulting from twenty years' experience in the treatment of cases of mental deficiency. He speaks, of course, of the importance of treating defects in the bodily condition before undertaking the moral and intellectual training. The bodily and mental deficiencies commonly met with in such cases are shortly enumerated, and treatment is considered under the following heads: (1) Attention to Hygienic Conditions; (2) Adaptation of the Principles of Medicine to the Infirmities which exist in this class of Patients;

Digitized by Google

(3) Improvement of the Physical Defects and Imperfections; and (4) Education and Training of the Moral and Intellectual Faculties. Under the second head the treatment of microcephaly by craniectomy is adversely commented on, the author agreeing with Dr. Bourneville's opinion in this matter. Reference is, of course, made to the successful treatment of cretins by thyroid extract. The book closes with a few remarks on the importance of the early commencement of training in such cases.

New Inventions.

THE THERMO-ETHER INHALER.

DR. CARTER of Weymouth has devised an ether inhaler made for him by Messrs. Krohne and Sesemann, of which figures are appended. It is constructed upon the same principle as Junker's inhaler for giving chloroform. It consists of two main parts—a water jacket with receptacle for a Japanese tinder cylinder, and a bottle like the Junker bottle, but graduated to hold two ounces of ether. As seen in the illustration, the water-jacket is suspended in front of the anæsthetist by a strap passing over the shoulder, and the ether bottle, placed in position, is about three-fourths of its circumference surrounded by the water-jacket, sufficient space being left for reading its graduation. About two or three ounces of warm water at about 100° F. are put into the jacket. This will be sufficient for one case, but if there are

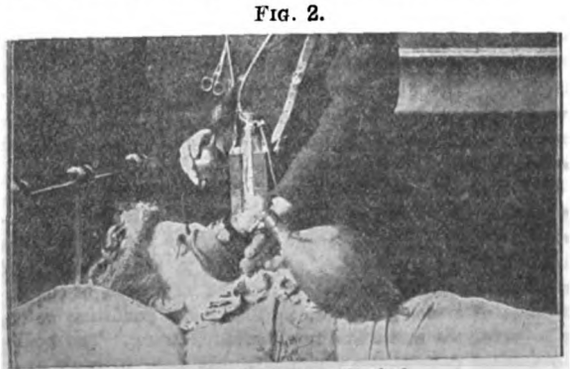

FIG. 1.

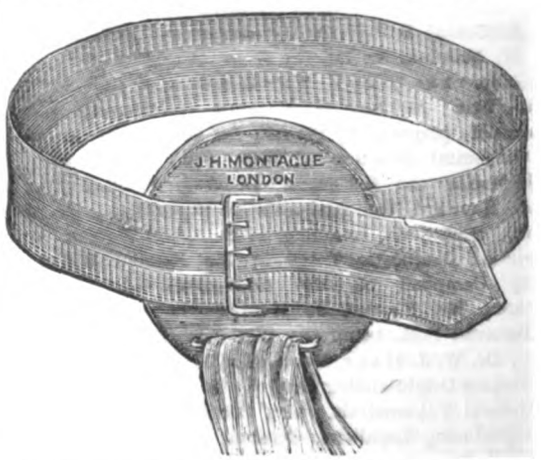
Inhaler without the bag attached.

several the temperature of the water may be maintained or increased by regulating the current of air passing over the lighted Japanese tinder in the cylinder, and thus causing a slower or more rapid smouldering of the charge. One charge lasts one or two hours. The air is pumped by means of the hand bellows through the ether, and when the patient requires a deeper anæsthesia than can be so obtained the "bag accessory" shown in the woodcut is placed in position. This is taken off and replaced as occasion requires.

FIG. 2.



Inhaler showing bag attached.

The advantages claimed for it are: 1. It produces little, if any, asphyxia; it is pleasanter for the patient both at the time of inhalation and subsequently; a cyanotic condition is rarely observed, its absence being due to pumping air through the slightly warmed ether. 2. The complete control over the ether it affords. 3. The ether is in view all the time and does not get contaminated with the products of exhalation; the residue of ether is little, if at all, altered from its original state, an advantage in cleanliness. 4. With management the ether can be kept at an equable temperature. 5. It reduces the equipment of the general anæsthetist—that is, if he uses Junker's inhaler for chloroform,—for pretty nearly the same apparatus does for both, with the addition of a Clover's bag, and substituting the thermo-ether bottle for the smaller chloroform bottle.

Eighteen cases, of which full notes were taken, in which the thermo-ether inhaler was used give the following results: The patients were all females aged from seventeen to sixty-two; all were in good condition save three, one of whom was "delicate," one had a feeble intermitting heart, and one was cachectic-looking, with a "weak heart." The average time of going under with this inhaler and Salomon's purest ether was 4·8 minutes. The operations were from 8 to 38 minutes' duration. Cyanosis only appeared once and the after-effects were few and trifling. There was a total absence of laryngeal irritation and coughing and perspiration. Dr. Carter is able to speak in favour of this inhaler, which, although producing anæsthesia more tardily than is usual, yet completely does away with the undesirable asphyxial symptoms which appear when some methods of giving ether are adopted.

POST-PARTUM UTERINE COMPRESS.

MR. O. T. SLATTER of Green-lanes, N., has submitted to us a useful addition to the gynæcological bag in the form of a pad invented by him and named "post-partum uterine compress," which is made by Mr. J. H. Montague of 101, New Bond-street, W. It consists of a concavo-convex round piece of metal six inches in diameter, padded and covered with white kid, which is kept in position by an abdominal belt made of webbing three inches broad connected to and buckling over it. The bar at its lower edge gives attachment to the sanitary towel or diaper, through a loop of which the belt is threaded posteriorly, the one thus

assisting to keep the other in place. The inventor claims for it these advantages: that after delivery it forms a firm and equable pressure (the amount of which can be regulated to a nicety), and is to be applied subsequently to manipulation and expression of the uterus in cases of imperfect contraction due to an atonic condition of its muscular walls, and in dilatation and flaccidity often met with in women of a neurotic temperament; that it is rapidly and most easily adjusted, no movement of the patient being required, retains its position, and enables the accoucheur to leave earlier and with a greater feeling of confidence, knowing that he has done all that is possible by way of prevention of post-partum hæmorrhage so far as pressure is concerned, which cannot be claimed for the old time-honoured ordinary binder, always difficult and often tiring to the female to adjust with any degree of accuracy, and equally useless on account of the impossibility of obtaining dependable pressure on the one part where only it is of any advantage. Lastly, Mr. Slatter does not represent it to be an instrument for compression only or to be applied to a non-contracted uterus, but to prevent redilatation of the organ after contraction.

THE LANCET.

LONDON: SATURDAY, JULY 20, 1895.

WE recently read in the *American Medico-Surgical Bulletin* an instructive article on Specialism by Dr. CHARLES B. MĔDING, in which the author does not seek to disguise the possession of uncompromising views. He declares much of present specialism to be empirical, and rather an art than a due combination of art and science. The tendency of all special treatment, he holds, must be to adopt local measures to the absolute exclusion of general considerations in diagnosis or treatment. A man who looks only into the ear cannot see far into the nose. He whose largest operation is the removal of adenoids will scarcely have a proper estimate of the possible urgency of a hæmorrhage, while those who view female life through the vagina will have little respect for the stomach. After explaining the increase of specialism upon purely commercial grounds, Dr. MĔDING remarks with much acuteness that "extravagant development leads to decline." It is upon this dictum that we desire to found a few remarks with reference to practice in our own country. The subject of specialism in medicine and surgery is such a well-worn one, and has been so often discussed in these pages, that it may be thought that nothing is left to say; but this is not so, for the position of matters has changed. There can be no doubt that a remarkable alteration in the position of the specialist is coming over London and the larger medical centres, and in our opinion this change will in no long period of time work a remedy of a condition of things in which many right-minded people have seen need for improvement. To use Dr. MĔDING'S words, extravagant development is leading to decline. With competition in specialism there will assuredly come an abatement of a certain desire to rush into specialisation that has of late seized upon the younger of our profession. The general idea that would seem to have pervaded the minds of practitioners and even students, that all specialism pays, is disappearing. When it prevailed it was dangerous, for as it is a simple matter for anyone to term himself a specialist upon any of the various orifices of the body he may elect as the one most congenial for his observation, the risk that badly endowed specialists should multiply with micro-organic rapidity could not be overlooked. And that such rash persons existed may be taken as proven by the frequency with which—at least so we are credibly informed—the two questions which follow are asked. Are needless operations performed for fees? Are methods of treatment urged upon patients for commercial rather than pathological reasons?

Now we are, as we should be, the last to go outside our legitimate domain to say anything reflecting on the character and status of members of the profession in whose behalf we ever write; yet we should be wanting to the trust that has been confided to us if we did not utter a word of warning. We know that practically neither abuse exists. Yet these questions have become matters of discussion in the profession, and this being so it is our duty to ask them out loud, furnishing such reply as is in our power. The practice of medicine and surgery is so inadequately rewarded in this country that the temptation to stray from the paths of rectitude is necessarily very great to those whom circumstances have contrived to make especially susceptible of the value of money. Acute competition may lead to sharp practice in medicine as much as in other avocations of a meaner sort and a more commercial nature. This much is admitted. But in spite of the admission we make bold to say that the answer to the two questions we have propounded is, and is emphatically, No. Here and there the medical man, as now and again the lawyer and even the priest, may be found so wanting to his trust as to give advice from the point of view of his own purse rather than of his patient's welfare—to deny this would be to claim for the medical man a universal and resplendent infallibility—but the profession at large is pure of such reproach—absolutely pure. Only one point requires our serious attention, and it is the point which has dictated all our treatment of this necessarily invidious subject. Is the small section of the profession known as specialists equally clean-handed? And, if so, has it always been, or do some of Dr. MĔDING'S pungent reflections upon the specialists of his own country recoil upon the specialists on this side of the Atlantic? The answer is contained in the incontrovertible proposition that only those men who have been educated, and have educated themselves by long and laborious work as all-round surgeons or physicians as a preliminary, can take a proper grasp of a special subject. Men may by circumstances and individual bent become specialists, but in fundamental knowledge and initial training their medical learning must be general, if they are to be first-class scientific authorities. A specialist whose learning and work have been of a limited character must perforce be narrow-minded, and will with perfect good faith advise an operation of which a fellow practitioner of wider views would see the danger in its disproportion to the condition; and we may safely assert that any consulting surgeon in large practice in London would be able to confirm the statement that not an inconsiderable portion of his time is spent in the useful work of pointing out the inadvisability of performing the very surgical exploit for the endurance of which the patient has been sent to him. But if this occurs often one unfortunate thing must follow: the reputation of the profession as a whole will suffer with the public. If it be known that the performance of a needless operation has been recommended, even though the motive may have been of the best, the public is not likely to condone the ignorance, or to see in the motive anything but evidence of corruption.

General practitioners have the matter largely in their hands. When one of their patients needs advice they cannot inquire too carefully into the reputation for special work of the proposed consultant before sending their patient to him or sanctioning an operation of any sort. That specialism in this country as in the United States has been over-developed there can be no doubt, but we venture to think that the writing is on the wall, and that the period of decline is at hand, and we are certain that it is in the hands of general practitioners to restore a healthy condition immediately. Special knowledge means

Digitized by Google

special training and special experience. Granted; but the more general and wide the learning upon which these are founded the more sound must be the claim to special skill. If this fact is properly recognised by the professional advisers of the public the temptation to the younger members of our order to arrogate to themselves the position of peculiar knowledge witnout the acquisition of sound general learning or the opportunities of first-class practical experience will be gone; the stress of over-acute competition in one or two popular branches of medicine and surgery will be abated; and the grounds for certain reproaches, now justly or unjustly urged, will be removed.

EXCELLENT though the motive may be, the practice of subscribing to every charitable scheme which well-meaning people may bring before the notice of the benevolent is often productive of harm. True charity, like mercy, carries with it a blessing to both the giver and to the receiver; but as mercy must be tempered with justice, so charity must be combined with prudence or it ceases to exercise its double beneficent *rôle*. At this time of the year benevolent people freely respond to the many appeals which are daily made for funds to send the children of our urban poor into the country for a holiday, and so far as this is carried out on right lines no form of charity can be more worthy of support. But these holidays are not always carried out on right lines; thousands of children are constantly taken by van or train for a day's outing to the country or to the seaside under conditions which are contributive neither to health nor to morality. This kind of treat is rightly deprecated by Canon S. A. BARNETT, who has done much for the social uplifting of the East-end, and who has contributed greatly to our knowledge of right methods in raising the status of the poor generally. We cannot do better than quote his own words. These children, he says, "crowd and scramble into the van or train; they scream and shout during the journey; they show by their greed of the best places a complete forgetfulness of their lessons in manners and unselfishness; and at the journey's end make a wild rush to the field or corner of the beach where the contractor has prepared the food he has brought from town. Here they are besieged by vendors of ices, sweets, whips, and whistles; they are hustled on and off donkeys or merry-go-rounds; they are called to listen to niggers and to concerts; they are tempted to penny 'shies' and shows. All this day, under the hot sun, fed on unwholesome food, excited by noise, they keep in the crowd to which they belong to breathe one another's breath. ..... At the day's end the children—weary, irritable, almost drunk with self-indulgence—once more crowd the carriages, and return home to show by noise and uncontrolled shouts that they have had a happy day." This is no exaggerated picture of what daily takes place during the summer holiday season, and as the tendency is to greatly widen the scope of these excursions year by year, nothing but positive harm can result whilst they are carried out under such conditions. The motive which prompts these good people to take poor children away from their squalid surroundings even for a day, and to place them in a healthier and purer atmosphere, is to be highly commended; but, however excellent the object, such outings as those described can only frustrate the result desired, for the children in many instances return home no better than they left, and in some cases, we fear, far worse.

The only remedy, as Canon BARNETT suggests, is to send the children in small parties in charge of a competent person, who should have absolute control over them, but far better would it be if the public, instead of subscribing to these day treats, would liberally support the already existing societies for sending children out of town, not for a day only, but for a fortnight. Of these there are many, and those who are interested in the matter—and all should be—will find a short but interesting account of the work which they do in the current number of the *Leisure Hour*. The well-organised holidays planned by these societies must do an enormous amount of good to the children both physically and morally, for not only is their bodily vitality renewed, but, their whole environment being changed, they are brought into contact with scenes and objects which otherwise they would possibly never see, and their minds receive an education not very dissimilar in effect to that which foreign travel has on those who can take advantage of it. So complete is the change to many of these poor children, so strange the scenes presented to the eyes whose only horizon has hitherto been formed by bricks and mortar against a leaden sky, that the impression produced on their brains is for ever afterwards present, and mothers have been heard to threaten that they shall never be sent for a holiday again, so wearying and incessant is their prattle of the things they have seen and heard. We cannot suggest a more striking contrast than that presented by the arrival home of the children after a fortnight's holiday, with the bloom of health upon their cheeks and full of tales of wonder, with the boisterous, mentally intoxicated, uncontrolled return of a party from the doubtful advantage of a day trip. As has already been said, no form of charity is more worthy of support than that which endeavours to minister to the health of the children of our urban poor, and while we earnestly trust that subscriptions may continue to flow freely in for this noble work, we hope that those who are tempted to subscribe to day treats will at least see that they are organised on a satisfactory basis—satisfactory both to the donors and to the recipients.

To the medical names on the national roll of valour—to the names of Surgeon-General Sir JAMES MOUAT, K.C.B., Surgeon HENRY THOMAS SYLVESTER, Surgeon-General Sir ANTHONY DICKSON HOME, K.C.B., Inspector-General JOSEPH JEE, Surgeon-General WILLIAM GEORGE NICHOLAS MANLEY, C.B., Brigade-Surgeon WILLIAM TEMPLE, Brigade-Surgeon CAMPBELL MELLIS DOUGLAS, Surgeon-Lieutenant-Colonel EDMUND BARON HARTLEY, Surgeon JOHN FREDERICK MCCREA, Brigade-Surgeon JAMES HENRY REYNOLDS, Surgeon-Captain JOHN CRIMMIN, Surgeon-Captain FERDINAND SIMEON LE QUESNE, Surgeon-Major OWEN EDWARD PENNEFATHER LLOYD, and Surgeon-General HERBERT TAYLOR READE, C.B.—must now be added the name of Surgeon-Captain HARRY FREDERICK WHITCHURCH, whose receipt of the Victoria Cross we announce in another column, for reasons tersely yet stirringly recapitulated in the official

Digitized by Google

gazetting of the honour, and perfectly well-known not only to all our readers but to all the nation. As a journal written for the medical profession, while we are properly anxious to dwell upon all topics by which honour may accrue to the profession, we are necessarily chary of outspoken laudation of any whole class or department of its members; but the enumeration of these names, redolent of the stories of their associated feats of valour, impels us to ask our readers to consider the singularly practical testimony that is thus afforded to the high qualities of our militant brethren.

The Victoria Cross was instituted after the Crimea by a Royal Warrant dated Jan. 29th, 1856, and was designed to be a visible reward for individual acts of bravery performed by officers, commissioned, non-commissioned, warrant, or petty, in the naval and military services, by marines, seamen, and privates. Three years later a further warrant declared that non-military persons who, as volunteers, had borne arms against the mutineers in India, should be considered eligible to receive the decoration. A complete list of those alive who have earned the V.C. shows that 179 persons can wear the justly coveted distinction—179 persons only. We are not intending to give accurate figures or attempting to express in mathematical terms the valour of the medical officer in our services as compared to that of his companion in war by calling attention to the proportionately huge share of Victoria Crosses that have been awarded to the officers of the army medical staff—the data for such accuracy are not forthcoming and the deductions would not be free from error—but we desire to point out broadly what this proportion is, using the figures of the estimates in the current issue of Whitaker's Almanac. At the present moment the standing Army of Great Britain numbers a little under 700,000, this figure includes the army reserve, the militia, the yeomanry, and the volunteers. The estimated total number of officers, seamen, coastguardsmen, and marines available for sea service in our Navy is a little over 80,000. Thus the total number of the men employed in the two services amounts to a little less than three-quarters of a million. If, then, all the Victoria Crosses now held (179) were held by persons still on the effective lists the proportion of decorated to undecorated in the whole army and navy would be roughly 1 to 4000. But 2500 of this three-quarters of a million are the medical officers who hold commissions in the two services. If the 15 Victoria Crosses held by the two medical departments were all held by officers on the effective list—the same supposition that we have made above in relation to the whole army and navy—the proportion of decorated to undecorated would be, roughly, 1 to 170.

The figures are in no way vitiated because the proportion should be calculated with reference to all the living servants of the Crown in either service, retired, pensioned, and on half-pay, and not only with reference to the effective lists; for among the retired, the pensioners, and the half-pay soldiers and sailors will be, of course, found a due proportion of medical officers. We do not wish to lay an improper stress upon these figures. We do not desire to take the reward of the Victoria Cross as the sole gauge of valour, and nothing could be further from our object in instituting these comparisons than any foolish idea of exalting our brethren in medicine at the expense of their brethren in arms. Our object has been solely to place before our readers an additional reason why the profession at large should be proud of its members in the services, who, albeit so-called non-combatants, have yet reaped on so many occasions the reward of personal valour in the field. In congratulating Surgeon-Captain HARRY FREDERICK WHITCHURCH upon the just recognition of his splendid and self-sacrificing deed of bravery, we congratulate him also upon being enrolled in a select band of heroes of whom the profession is justly proud—the medical holders of the Victoria Cross. He is a good companion in right good company.

Annotations.

"Ne quid nimis."

THE DUTIES OF MEDICAL SOCIETIES.

IN the account of the meeting of the British Gynæcological Society which was published in THE LANCET of July 6th, it is stated that the first business of the society was to witness three specimens: (1) that from a case of suppurating ovarian tumour with purulent peritonitis and adhesions; (2) fibroma of the uterus removed by enucleation; and (3) total extirpation of the uterus and ovaries for prolapse. With regard to the third case a few remarks are, we think, called for. The surgeon who narrated the case explained that for the prolapse he tried the use of pessaries, and not succeeding therewith he decided to remove the uterus and appendages, the patient being a woman aged thirty. We do not pretend to write as gynæcologists; but we do not for that reason feel it at all less binding on us to say that in our opinion the reasons for this procedure require to be more fully set out than appears to have been done at the society. We note that the president (Dr. Godson), Dr. Routh, and Mr. Taylor of Birmingham criticised the procedure in a tone of disapprobation. Ordinary surgery has become more conservative with its increased powers. The removal of a leg is felt to be an unsatisfactory and opprobrious proceeding, except as a last measure of relief. *A fortiori* any operation involving a much more serious mutilation must be so regarded, and we are of opinion that a society before which such cases are recorded does not discharge its duty without investigating the case by a committee appointed for the purpose, and placing its deliberate judgment on the facts on record. The amount of suffering and disability experienced by the woman, the precautions taken by the surgeon before operating, and the degree to which he shared his responsibility by consultation and by full statement of the facts to the patient are obvious matters for inquiry. We gather that the operator acted with perfect satisfaction to himself in what he did, and doubtless when the full facts are known we shall find with perfect propriety. But for the sake of the reputation of surgery, and especially of gynæcology, we maintain that the facts should be fully investigated and published by the society, which has in a degree incurred responsibility in connexion with the case.

FUNERAL AND BURIAL REFORM.

IT is satisfactory to see from the reports of the Church of England Burial, Funeral, and Mourning Reform Association that efforts are being concentrated on those two points where reform is most needed. Those are the coffin and the grave. In other words, burial is gradually coming to be a

Digitized by Google

reality and not a sham. It is no longer necessary to attach the scarves, hat-bands, plumes, and palls; these relics of undertaking frippery have almost disappeared, and it is no use slaying the slain or even the moribund. The coffin still requires reforming. In his immortal work, "Vanity Fair," Thackeray observed: "As long as we have a man's body we play our vanities upon it, surrounding it with humbug and ceremonies, laying it in state, and packing it up in gilt nails and velvet." In "The Newcomes" he returns to the subject, and at the funeral of Lady Kew refers to that "bedizened box of corruption" and "yonder velvet-palled box spangled with fantastic heraldry and containing within the aged slough and envelope of a soul gone to render its account." Is there not still a lingering relic of these "vanities" in the strong oak coffin with French polished sides and lid and shining brass furniture? For if the burial is to be a reality, and if the body is to be committed to the ground, the handsome coffin surely becomes an incongruity. This last lingering relic of undertaking monopoly will die very hard; but die it must when its absurdity once becomes patent. Perhaps there is some feeling for the undertaker shorn of all his other profits but this, and some echoing of the question of the elder Mr. Weller, "What would become of the undertakers?" Possibly some persons argue that the providing of handsome coffins gives employment, and therefore bread, to a larger number of persons than if they were of a simpler character. These and all other excuses—reasons they cannot be called—must give way to what is expedient. If burial is to continue as a means of disposal of the dead, it must be, as defined by Lord Stowell, the carrying of the body to its parent earth for dissolution in a decent and inoffensive manner. The use of a readily perishable coffin becomes every day more and more imperative, bodies entombed in vaults and bricked or walled graves being a source of danger to the living as well as a mockery of burial. And the strong coffin, when deposited in the earth, has the disadvantage of retarding the dissolution of the body and defeating the very object for which it is placed in the ground. Wood, whether in the form of oak, elm, or deal, will always be required for the living, and if the provision of a perishable coffin should create a new industry so much the better. Then there is the question of expense. Is it reasonable that the coffin, the very name of which implies "basket" or "wicker," should cost a sum varying from £5 to £20? A coffin sufficient to convey the poor body to the grave could be provided for less, leaving the balance for survivors.

THE GENERAL ELECTION.

"Election, election, and reprobation—
It's all very well, but——."

So sang a great poet, using the words in their theological sense; but they may well serve as a text at the present time when there is a great deal both of election and reprobation on foot throughout the country. Medicine has, or ought to have, no politics. Its sphere of labour is the same whether east or west, and disease attacks every class and creed with absolute impartiality. Still, all medical men must remember that they are citizens as well, that citizenship brings with it responsibility, and that this responsibility must not be shirked. We all have our own private views as to what things are desirable and right, but in a general election there are certain broad issues which touch every man, on which everyone is bound to give his judgment, and which stand out above the flood of petty personal wishes and interests. A word of warning may be said upon political excitement, to which three deaths at least have been set down during the present election. The turmoil and stress of modern life, perhaps, tend to unsettle those whose nervous system is not very strong, and the tendency to over-pressure which has been a feature of national education for the last twenty years or so has no doubt succeeded in producing a generation of nervous, irritable, and mentally ill-balanced men. The average school-board taught voter, from the age of eight to thirteen or so, is crammed with scraps of knowledge most of which are utterly useless to him in after life, and this cramming naturally reacts on a brain ill-nourished, and so lays the foundation for future nerve troubles. The old kind of election, such as those described in "Handy Andy" and "The Newcomes," doubtless presented a variety of undesirable features. The drink, the bribery, and the free fights have all passed and gone; but are matters really in a more healthy state—physiologically, we mean? In an election nowadays attention and excitement are kept perpetually on the stretch by news coming from far and wide. No wonder, then, that when the inevitable reaction arrives its results are shown by increased attendance at hospitals for sleeplessness, headache, and other forms of nerve fatigue. We would counsel, then, our readers, as forming an important part of the body politic, to use their privileges dispassionately, to vote for the side which they think right, and not to be led away by the clamour of rival party newspapers, but also to bear in mind that the Parliamentary vote is not a thing to be thrown lightly into the political cauldron, but one to be used with discretion, and that if the issue is decided by these means it may be said of our country, even as of another long ago, "And the land had rest forty years."

ALPINE MISADVENTURE.

WE have before us the official report of the "Saison Alpinique" in Switzerland for 1894, from which we learn that the deaths by misadventure on the Alps were in all thirty-seven. This total is a little below the yearly average, which, according to the same authority, is forty-one. Of four out of these thirty-seven "accidents" there are no details; but as to the remaining thirty-three, we know that fourteen persons had fallen over precipices; that eight met their deaths on comparatively easy routes; and that six were the victims of their own imprudence, from having ventured on dangerous tracks. Finally, one climber slipped into a crevasse from which his corpse was recovered, two were crushed to death by the descent of avalanches, and two others by the fall of rocks. This, however, by no means exhausts the list of those who have shortened their days by ascending to Alpine elevations. Cases of heart failure, due to "high tension" at "high altitudes," have been frequent enough to evoke a medical warning against the practice, so recklessly indulged in by gouty and atheromatous subjects, of getting "ballooned up" by funicular railways to points at or immediately under the snow-line. Indeed, so common has fatal syncope from this cause become that two years ago a Congress of Swiss physicians met at Arosa to formulate their protest against the multiplication of such means of rapidly conveying passengers in all states of health to elevations at which only the young and sound can respire with ease and safety. Powerless to arrest railway enterprise, the Congress suggested that at the departure and arrival stations of those lines the companies should have medical aid within immediate call, with the appliances and restoratives necessary. Many of the adventurous middle-aged might, before gratifying their ambition to ascend the Jungfrau, for instance, have themselves examined as to their fitness for the ordeal; others, in whom heart failure had declared itself on arriving at their destination, might, by prompt and effective treatment, be rescued in the nick of time. Had such a preliminary examination been practised in the case of Baron Peccoz, whose tragic death in the presence of the Queen o Italy on the Lysjoch last autumn was described in THE

Digitized by Google

LANCET, he would certainly have had full warning of the fate he was courting. As it turned out, his condition was such that his death should have found its place among those due to syncope, instead of being classed, as it was, in the list of "accidents." The fact suggests considerations of the highest medical interest, such as might well engage the attention of another Congress like that which met at Arosa. How many cases of slipping down crevasses or falling over precipices are not really the result of antecedent heart-failure supervening suddenly in a perilous position? That is the question on the solution of which will depend a system of classification totally different from that adopted in the report of the "Saison Alpinique" for 1894.

AN EXAMPLE TO BE FOLLOWED.

"WHAT Lancashire thinks to-day England thinks to-morrow," is a saying much in evidence at the present moment, and we may hope that this remark will hold good of at least one other matter whatever may be the case as regards party politics, with which we are not concerned in these columns. It had been for many years the custom of the members of the legal and medical profession in Preston to have an annual cricket match, and some three years ago it was decided to combine this match with the social function of a garden party. The event became very popular, and on the occasion of this year's match some 1200 invitations were issued. The expenses are met by the two professions, not merely the players, but by all the practising members, so it is easy to see the good fellowship and *camaraderie* that exist, not only between individual members of each profession, but also between the two bodies in their corporate capacity. We think that the example of Preston might well be followed by other large towns, for any opportunity of inducing professional men to take interest in subjects outside their daily toil is not only a benefit to themselves, but also to those for whom their work is done, inasmuch as by such mental and bodily recreation they are prevented from getting into what a prominent medical man recently called "grooviness." In the single innings match which has recently been decided we notice that the medical men won by 63 runs, the scores being—"Medical," 121; "Legal," 58.

PROPOSED MEMORIAL TO PROFESSOR HUXLEY.

THOUGH we hope shortly to see a national memorial raised worthy of that great man of science who recently passed away from us, yet it is none the less fitting, we think, that the students and friends of the medical school where Huxley commenced his scientific studies should establish among themselves some form of lasting testimony which, if it had no other object in view, may at least be calculated to inspire the future students of Charing-cross Hospital with that excellent spirit of scientific progress and love for the truth and the truth only which was so marked a characteristic of the late Professor Huxley. We are glad to learn that the interest in the proposed memorial is not likely to wane. At the meeting which we announced to take place in our last issue at the Charing-cross Hospital Medical School on the 16th inst. there was a good attendance, and letters expressing inability to attend, but the tenour of which was in sympathy with the movement, were read by Mr. Herbert Waterhouse, the secretary, from the Duke of Saxe-Coburg, Sir Guyer Hunter, Mr. Henry Huxley, Sir James Paget, the Hon. W. F. D. Smith, M.P., Mr. John B. Martin, Sir Savile Crossley, Dr. T. Henry Green, Dr. Mitchell Bruce, and others. Sir Joseph Fayrer, who presided, gave a short but impressive sketch of the friendship which subsisted between himself and Mr. Huxley while students together at Charing-cross Hospital. He claimed to have largely influenced Huxley in the choice of a career. After a warm eulogy of the splendid abilities and personal qualities of the distinguished student of nature Sir Joseph Fayrer moved: "That it is desirable, by means of a suitable memorial in connexion with the Charing-cross Hospital Medical School, to permanently record the fact that the late Professor Huxley received his early scientific and the whole of his medical education at the Charing-cross Hospital School, and thus to keep the example of his life and work constantly before succeeding generations of Charing-cross students." This was duly seconded and carried. In accordance with the terms of a further motion proposed by Mr. Barrett, and seconded by Dr. Watt Black, it is proposed that the memorial shall take the form of a Huxley scholarship and medal, to be awarded annually at Charing-cross Hospital Medical School, and that if funds permit an annual lecture at the Charing-cross Hospital Medical School dealing with recent advances in science and their bearing upon medicine shall be instituted. We learn that subscriptions have already been received which it is hoped may meet the requirements of a scholarship and medal, and the committee trust that funds sufficient to establish the annual lectureship will be forthcoming. The scheme is a worthy one, and we trust that no part of it will languish for want of adequate support.

ENGLAND'S QUARANTINE STATION.

ONE intended piece of legislation has unfortunately to be postponed until next year owing to the sudden dissolution of Parliament. Last year the House of Commons was promised that they should never again have submitted to them in the Estimates the item for maintaining an establishment and staff under the Quarantine Act; and it is no secret that a Bill had been drafted, and was to have been brought in by Sir Walter Foster, in order to settle once for all that England would no longer maintain even a semblance of quarantine, whether for commercial or international purposes. Now the matter must stand over, and in addition to the reproach so often levelled at us of possessing Crown colonies which maintain the system of quarantine in the Mediterranean, we are still open to the retort that the hulks at the Motherbank are a standing proof that, whatever our motive, we have not finally abolished quarantine in this country in connexion with yellow fever. It is to be hoped that at an early date in the Session 1895–96 steps will be taken to remove this blot from our statute-book, and that the fulfilment of the promise made by the last Government will not be delayed.

A GROWING DEMAND FOR LIGHTER WINES.

AN interesting return of statistics, giving, degree by degree, the strength of wines imported into this country during the year 1894, has recently been printed in response to an order of the House of Commons. From the point of view of the evils of alcoholic drinking it is especially interesting, since the figures show pretty conclusively that the demand of the people is steadily increasing for lighter alcoholic beverages, and it is a fact on which we think the nation may well congratulate itself that the supply of wines of a lighter and more wholesome character is sufficiently met as to present no obstacle to this healthy movement. Taking the total wine imported in cask, it will be found that 7,503,044 gallons were imported of a strength not exceeding 30 degrees, while of a strength exceeding 30 degrees, up to 42 degrees, and beyond, 4,596,283 gallons were imported into this country. Spain sends to our shores the largest quantity of wine (3,748,974 gallons), but it is distinctly stronger than the generality of French wines. Thus, the strength of the highest proportion supplied (677,753 gallons) was 28 degrees (11 degrees more than the bulk of French wines). France stands

Digitized by Google

next in regard to the total quantity imported, but the largest proportion of the importation (855,634 gallons) consisted of wine of 17 degrees strength only, the supply of wine of greater strength than 30 degrees being quite insignificant, till it falls to absolutely *nil* after 38 degrees. Portugal supplies almost as much wine as France, but here again the bulk of it is stronger even than Spanish wines. Thus, the highest figure representing gallons imported occurs in the 35 degrees strength column. Coming to our Australasian colonies, whose supply in regard to quantity stands next, it is again satisfactory to find that the largest number of gallons imported stands at 24 degrees strength. These results will surely convey a crumb of comfort even to our strictly abstemious friends; but if, as M. Daudet is said recently to have stated, the ravages of the phylloxera and the consequent fabrication of alcoholic liquors, which to a large extent replaced the supply of light and wholesome wines, are leading to distinct increase of crime in France, then we may with some justification regard these figures as sure and certain evidence of moral progress.

MODERN MEDICINE AS A SCIENCE.

THE claim of medicine, in some of its departments at least, to take a place among the exact sciences has just been ably vindicated by Dr. Alfred Carter of Birmingham. Writing in the current number of the *Birmingham Medical Review* he adduces several familiar instances in which from given conditions certain phenomena may be confidently predicted. No doubt many branches of medical inquiry are still in the inductive stage, and the laws which operate therein have yet to be worked out, but the same condition of incompleteness exists more or less in every one of the natural sciences. Modern medicine has a rational and scientific basis. This is Dr. Carter's theme, and he justly condemns the narrow utilitarian views according to which a student's hospital work should be devoted solely to the acquisition of so-called practical experience. Considering the multiplicity of intricate subjects with which a student has to gain some acquaintance in the space of five years, it should be his object to grasp general principles and to lay the foundations of a stock of knowledge which more mature experience will enable him subsequently to increase.

MEDICAL EDUCATION IN THE UNITED STATES.

THE efforts of the best men in the profession of the United States to raise the tone and standard of medical education there have often been alluded to in our columns. The case of the United States is singular as that of a settled, well-ordered community of over fifty millions, mostly English speaking, in which there is no central law governing the practice of medicine. Each State does what it pleases, and most of them please to do very little in the way of exacting from medical practitioners any evidence of sufficient or satisfactory education, either general or medical. There is no central endowment of medical schools or universities with which medical schools are connected. Any group of needy or enterprising men may combine in any town or State to create a medical school, and till lately have had no difficulty in getting it recognised after a fashion. In this way it has come to pass that "in this unhappy country," as Artemus Ward would say, there is an unprecedented number of medical schools and of medical practitioners, charlatanism triumphs, and the reputation of the profession suffers. Whereas there is in the Austro-Hungarian Empire 1 physician to 3857 people, and in England and Wales 1 to 1484, in the United States there is 1 to 500. So with medical schools. In the Austro-Hungarian Empire there is one medical school to 5,153,917 of the population; in Great Britain one to 2,358,767 of the population; and in the United States there is one medical college to 440,151. There is no general medical council to supervise all and to see some sort of fair play to all. The results have been disastrous. But the evil is now too faithfully admitted and exposed to be of much longer continuance. The last statement of it and of the attempts to remove it are to be found in an admirable "Plea for Efficient Legislation Regulating Medical Practice," read before the American Academy of Medicine at Baltimore on May 6th, by Perry H. Millard, M.D., of St. Paul, from which we take most of the above figures. The reformers began with requiring a curriculum extending over three years. They now aim at requiring six months' courses in separate years for four years and propose to exact this after 1896. They recognise that legislation is indispensable to secure this, and that it is necessary in the interest of the public and of the medical profession alike. What can be more obvious than the truth of these views? How can men be expected to cultivate medical learning and efficiency if every charlatan is allowed to use medical titles and to enforce medical charges? The anomaly of low medical education in the States is the more remarkable, Dr. Millard shows, as the founders of the United States showed their wisdom in establishing a system of common school education that challenges the admiration of the world. The promoters of sound medical education in the United States deserve all sympathy, and they have it. They must appeal boldly to high public sentiment in their own country for powers to control the number of medical schools, and to secure a good minimum of preliminary and medical education in all who call themselves medical practitioners, and for the body or bodies with such powers of control the power of censuring or degrading those who act unworthily of their high calling.

THE REWARDS AND HONOURS FOR CHITRAL.

No one who has followed the history of the heroic defence of Chitral and of the splendid efforts that were made for the relief of that garrison can deny that all who took part in it deserved well of the country. It adds another and a very brilliant chapter, of which any nation might well feel proud, to the long record of successful and distinguished military services of the British in the East. England has become an empire and has extended her boundaries from sea to sea and land to land by the possession of those qualities—force of will, pluck, and fortitude—which were probably never better exhibited than on this occasion. The forces that took part in the defence and relief of Chitral defied climate and disease, and laboured under a tropical sun or amid snow and icebergs with the same indomitable perseverance, scornful alike of obstacles and difficulties, ready to fight and unconscious of defeat. Their services belong to history, but we are proud to point to the fact that members of the Indian Medical Service were among those who most distinguished themselves. We sincerely congratulate Surgeon-Major George Scott Robertson, C.S.I., of that service, on being made a Knight Commander of the Most Exalted Order of the Star of India, and Surgeon-Captain Harry Frederick Whitchurch, also of the Indian Medical Service, on his having obtained the decoration of the Victoria Cross for his conspicuous bravery during the sortie from Chitral Fort on March 3rd last. The brief history of the circumstances under which Her Majesty has been pleased to confer this much-coveted decoration on Surgeon-Captain Whitchurch can only be read with a glow of pride and a feeling that he has thoroughly earned it. Sir George Scott Robertson, who is attached to the Bengal Medical Department, was appointed surgeon on March 30th,

Digitized by Google

1878, and subsequently became a surgeon-major. He displayed great courage, ability, and judgment under very trying circumstances throughout the siege of Chitral. We have previously alluded to the splendid services of Colonel Kelly, who, in our opinion, has not been sufficiently rewarded for them. We sincerely congratulate him, however, and all the other officers who played a distinguished part in the operations of the Chitral Expedition on the recognition of the brilliant and important services they rendered. It is presumed that in a subsequent *Gazette* the services of other portions of the Expeditionary Field Force will also be recognised and rewarded.

JACKSONIAN EPILEPSY FROM OLD CEREBRAL ABSCESS.

DR. LEPINE has recorded, in the last number of the *Revue de Médecine*, a curiously interesting case of a woman aged sixty-two who, ten years before her admission to hospital, had had a series of convulsions with loss of consciousness, and these were succeeded by left hemiplegia, which lasted fifteen days. Since then she had had frequent attacks, which had been regarded sometimes as Jacksonian attacks, sometimes as hysterical. In December last she had one day several attacks, and these continued to recur day after day. There was loss of consciousness in the severe ones, but there were also slighter ones in which there were jerkings of the fingers and forearm, but no loss of consciousness. On the day after her admission, following a severe attack, left hemiplegia was noted affecting both arm and leg, but sparing the face. The attacks came on more frequently, and although bromides lessened their severity it did not control them, and the patient gradually sank and died. At the necropsy it was found that in the right frontal lobe, rather nearer to the anterior border of the hemisphere than to the fissure of Rolando, there was a cyst two to three centimetres in diameter with caseous contents. It was, in fact, apparently a cold abscess, and there seems every reason for believing that it must have existed for the ten years during which symptoms, only explicable on the hypothesis of such a lesion, had been present.

TREATMENT OF THE OPIUM HABIT.

IN a recent number of the *Philadelphia Medical News* Dr. M. V. Ball has a short note in reference to the treatment of what practically amounts to a disease by the sudden withdrawal of the opium and the withholding of treatment for the severe symptoms which sometimes follow its removal. He briefly relates the histories of three patients treated in this way. The first was a man aged twenty-six who had been an opium smoker for four years; the second, a man aged thirty-six who had been taking twelve grains of morphine daily for twelve years; and the third, a man aged thirty-one who had used gum opium, laudanum, and morphine for fifteen years, taking about 50 cents' worth in a day. All three had been convicted of crime and were treated in the Eastern Penitentiary. They were carefully searched, all intercourse with the outer world was prohibited, and they were fed on the ordinary prison fare. The sudden deprivation of the drug produced the usual symptoms—severe diarrhœa, vomiting, and insomnia, as well as weakness and irritability. The patients were visited daily and reassured, but no drugs were administered. Within ten days all desire for the drug had ceased, and the symptoms alluded to had passed off. The loss of flesh was soon made up, and they declared themselves as feeling better than ever. Dr. Ball has now treated six cases in this way, and is inclined to think that this mode of treatment by sudden and complete withdrawal of the drug, without any symptomatic or dietetic treatment, is followed by as speedy and satisfactory results as any other course. One curious point which he mentions is that in several cases in which the drug has been gradually withdrawn and the emesis and diarrhœa treated with other medicine the suffering, although not so acute, was prolonged, and the desire for the drug persisted for a much longer time. As Dr. Ball remarks, the treatment here recommended is only possible under conditions in which restraint can be used.

MEDICAL CERTIFICATES FOR THE LONDON BOARD SCHOOLS.

THE following incident took place at the Board meeting on July 18th:—Mr. Athelstan Riley asked the chairman of the school accommodation and attendance committee whether, since the letter received from Captain Blount, R.N., secretary of the Victoria Hospital for Children (stating that, until the resolution passed by the Board on May 30th, 1895, is rescinded, the staff will decline to give certificates to children attending the hospital, though they may think it desirable that the child should be excused from attending school), the following letter had been received from the secretary of the Paddington Green Children's Hospital:—

"10th July, 1895.

"GENTLEMEN,—I am desired by the medical staff of this hospital to inform you that, should the resolution passed by your board on May 30th, 1895 (a copy of which I enclose) be carried into effect, they will decline in future to give medical certificates of unfitness to attend school for children under treatment here."

To the foregoing question Mr. Sharp (chairman of the School Accommodation and Attendance Committee) answered "Yes." There is a simplicity and directness about Mr. Sharp's answer which it would be a pity to spoil by any comment.

THE ORGANISATION OF GENERAL PRACTITIONERS IN GERMANY.

OUR readers will have been much interested in the account given in THE LANCET of last week by our Berlin correspondent of the proceedings at the annual meeting of the German Practitioners' Association. The association, which is purely voluntary in its nature, concerns itself rather with the social interests of the profession than with scientific matters. It would almost seem as if one association, however large, were unfitted to discuss both social and scientific questions. The British Medical Association has never succeeded in organising discussions on questions of general professional interest, affecting general practitioners as it has succeeded in the sections devoted to scientific work. Division of labour applies to associations as it does to individuals. The chief feature of the General Practitioners' Association was the address of the president, Dr. Aub, who pointed out that the Workmen's Insurance Laws, by which every workman is compelled to be a member of a sick club, have materially affected some departments of medical practice. Individual medical men find it hard to compete against the clubs. The association is utilised to treat with the clubs as to terms, treatment of medical officers &c. Surely in this country there is room for the action of a large and powerful defence association for protecting medical men from the unfair dictation of associations of workmen who fail to realise the nature and value of medical service. The one remedy for the crushing and humiliating pressure brought to bear on our own members is the organisation of the profession for dealing with these powerful associations of workmen. One point was much discussed with reference to the number of medical officers that a sick club should have. In a few districts what is known as the "free system" (described in THE LANCET of Feb. 2nd) is in force. According to this plan every practitioner in the district of a club who chooses to do so is allowed to attend the members. After a warm debate a resolution recommending the adoption of the "free

Digitized by Google

system" throughout the German Empire was adopted. To avoid unjustifiable demands on the part of the club it was strongly advised in the resolution that contracts with it should be made, not by individuals, but by the Association, which has branches all over the country. We commend this association and its proceedings to the attention of the many medical men who are now justly anxious about the interests of the profession. It is only fair to say that the educational and professional efficiency of medical men was insisted on by the President. In this connexion Dr. Aub pointed out the deficiency of the qualifying examinations, especially in respect of mental diseases. This deficiency had been shown in courts of law in Germany to the disparagement of medical witnesses and the discredit of the profession.

A SALVATION ARMY SHELTER AND SMALL-POX.

DURING the last fortnight 13 cases of small-pox have occurred in the district of St. George the Martyr, Southwark, and of these 5 came directly from the Blackfriars Salvation Army Shelter. Several of the cases also occurring in the workhouse sprang directly from the original patient, Benjamin Levi, whose case was reported on June 19th. Besides these cases others have been reported from the districts of St. Giles, Limehouse, and Whitechapel, all occurring in patients who had slept in the shelter during the period of infection. Five cases which had been exposed to infection in this particular shelter were also reported by the Asylums Board. After the reporting of Benjamin Levi's case the medical officer of health (Dr. F. J. Waldo) determined to inspect the shelter, and attempted to do so on the night of June 24th in company with two sanitary inspectors. The party were refused admission, and accordingly a justice's warrant to enter and inspect the premises was obtained on July 6th. Armed with this warrant the party proceeded to the shelter on the morning of July 8th, and were forcibly prevented from entering, but on a threat of bringing up a strong force of police Dr. Waldo was allowed to enter, when, to use his own words, he found "overcrowding of the grossest character along with utterly inadequate ventilation." The St. George's Vestry have passed a resolution to serve a notice on the occupier of the shelter to abate the nuisance. This is as it should be, and we only hope that steps will also be taken to punish those who forcibly resisted the entry of the medical officer. Sanctuary for tramps and valiant beggars used to be the peculiar privilege of the Church, and now that this is in abeyance the right must certainly not be given over to a body which has assimilated the worst excesses of primitive and mediæval mysticism, and which, if allowed to go on its way unchecked, will be a danger to the health of the community.

THE MATERNITY CHARITY AND DISTRICT NURSING HOME, PLAISTOW.

THIS charity dates from 1889, when Sister Katherine, the Lady Superintendent, went to Plaistow and started the institution in coöperation with the parish authorities as one of the charities of the parish of St. Mary's. The work soon extended over eleven parishes. Maternity cases have been nursed for thirty-four medical men, and district cases have been nursed for seventy-four medical men. We are glad to see that the authorities of the charity approve of the poor being attended where practicable by medical men. They properly observe that even among the poorer classes there are many women who can afford to employ a medical man at their confinement, and that such an arrangement is desirable. We agree with this, and regard all midwifery practice not under the care of a medical practitioner with some misgiving; but in such districts as Plaistow it seems that about half the population cannot afford even a half-guinea fee. It is for them that a maternity charity exists. The cases are attended by nurses and midwives; various medical men give their assistance when necessary. There is besides a large amount of district nursing. There were 1088 midwifery cases. Of other cases there were 1540, the whole involving 986 special day attendances and 1095 special night attendances, and a total of 63,478 visits. The poverty of this district has been emphasised in the last winter, and we cannot but think that such charities as the above have a strong claim on the benevolent of all parts of London. They are in considerable debt, and help will be very gladly received by Sister Katherine.

THE LATE PROFESSOR HUXLEY.

THE *Spectator* of the 13th inst. contains a communication illustrative of the kindly sympathy of the late Professor Huxley with the efforts of obscure scientific investigators. It appears that a man of the labouring class devoted his spare time to original research, aided by a sixpenny magnifying glass, and that he had forwarded a paper to Professor Huxley giving a vivid and scientifically accurate description of the multiplication by fission of a lowly organism observed by him in an infusion of his own preparation. It was suggested by a clergyman, of whom Professor Huxley had inquired how he could best help such a man, that the gift of a microscope and a few scientific books would probably be very acceptable in the meantime. These were duly forwarded, and a splendid microscope and some books were handed over to the labouring man as a gift from an unknown hand. The gratified recipient, however, shrewdly guessed the source whence the gift came, with an expression of extreme satisfaction at the generous interest and kindly sympathy it evinced.

QUACK DOCTORS IN INDIA.

MR. R. CARSTAIRS, of the Bengal Civil Service, after an experience of many years as a magistrate in the Mofussil, has produced a remarkably interesting work entitled "Human Nature in Rural India," which is published by Messrs. William Blackwood and Sons. Books treating of Indian topics have become rather numerous of late years, but the writers, for the most part, select some salient point or special characteristic as their theme; whereas in the present instance there is no attempt whatever at striking novelty or attention-compelling originality, the writer contenting himself with the production of a sober-tinted picture wherein the actual life led by the vast majority of the inhabitants of our great dependency is faithfully depicted. The province of Bengal, with which Mr. Carstairs is chiefly concerned, is by far the most densely populated portion of the huge peninsula, but its teeming millions are utterly devoid of all ambition, and have no hopes or desires beyond the petty horizon of their native villages. They seem to be a people of an unalterable type, upon whom climate and food (aided doubtless by unbridled sensuality) have affixed the seal of inertia, depriving them entirely of self-reliance, energy, and capacity for self-government. In common, we imagine, with most people in this country we were under the impression that the shroff or usurer was the principal scourge of the Bengal villager, but according to Mr. Carstairs this much maligned individual is in reality a blessing in disguise, being as a matter of fact far too wise to slay outright the geese that lay him silvern eggs. He charges a high rate of interest, it is true; but where are there money-lenders to be found who will distribute their stock-in-trade for love? And often, if it were not for his timely aid, the peasant would be irretrievably ruined. A far worse friend to the native is the quack doctor,

Digitized by Google

who of late years has multiplied at an astonishing rate. Formerly the species was unknown save in the larger towns, but nowadays the creature is to be met with everywhere, making money chiefly by the sale of medicine, but also extracting fees whenever he can induce his patients to disburse. Mr. Carstairs characterises the Bengal quack as a "reproach and a hindrance to English medicine," and states that in one village of about two thousand inhabitants with which he is acquainted there are no fewer than sixteen of these irregular practitioners.

THE PROFESSION AND FORCED STATE LABOUR.

ALBERT SMITH in one of his novels describes the opening address at one of the London hospitals, wherein the speaker, a prosperous consultant, pointed out how the future practitioners would receive their reward, not perhaps in the wealth that perishes, but in the consciousness of duty done, and the feeling that they had done something to lessen the burden of human misery. Many members of all the professions do work for nothing, but the medical profession not only do this but are forced to do so by the State for its own benefit. This we have no hesitation in saying is a gross injustice. During the recent election at Bradford a series of questions bearing on this matter was submitted by some medical men in the town to all the candidates. The Liberal candidates either gave no answer or a very vague one. The Unionist and Labour candidates expressed themselves opposed to forced labours exacted from medical men. In the result Bradford sent three Unionist members to Parliament, and we may hope that the step taken by the Bradford practitioners may be the first towards recognising that the medical profession does bear an unjust burden.

A BATTLE OF THE CLUBS AT BRUSSELS.

A GRAND struggle is taking place in Brussels between the medical profession and the clubs—a struggle which is due to much the same cause as that recently occurring in Cork, viz., the admission of well-to-do people who are quite able to pay ordinary medical fees into clubs where the payment to the medical men, though it may perhaps be all that a labourer or mechanic can afford, is quite unremunerative. The Brussels College of Medical Men is determined to stand by the club surgeons and to assist them pecuniarily. Negotiations have been carried on for some time past between the club official delegates and the representatives of the Medical College, but recently they came to a termination, with the result that every club surgeon in the district resigned on the 6th of this month, refusing to attend anyone but those on whom he was actually in attendance. This has made the clubs offer all kinds of inducement to outside medical men, but fortunately, as far as our last information goes, they have not been enabled—as the Cork clubs were—to find any medical men willing to accept such an invidious position as they offered them. It it to be hoped that this united action of the Brussels club officers will result in all persons, except the really poor, being compelled to pay reasonable fees for their medical advice, for, as the editor of the *Scalpel* remarks, it is altogether wrong that men belonging to the Commercial Travellers' Society, some of whom are known to have more than £1000 in the funds, should get medical advice for themselves and their families for 1*s.* 8*d.* a year.

A CORRECTION IN MEDICAL BIBLIOGRAPHY.

MR. BAILEY, the accomplished librarian of the Royal College of Surgeons of England, has just made a discovery which will be of considerable value to those who are interested in the medical bibliography of last century. Dr. John Elliot, a native of Edinburgh and graduate of St. Andrews University, became a Licentiate of the College of Physicians of London in 1762, and soon acquired a lucrative metropolitan practice as well as a good social position. His only misfortune seems to have been that Mrs. Elliot was much younger than her husband and addicted to frivolity, which resulted in a divorce after three years of wedded life. Dr. Elliot was knighted by George III. in 1776, was created a baronet in 1778, and became physician to the Prince of Wales. He resided in Cecil-street, and died in Hertfordshire in 1786. His biographers have hitherto attributed to him the authorship of six treatises, including an edition of the works of the celebrated Dr. Fothergill; but Mr. Bailey shows conclusively in the current number of the *Athenæum* that the real writer of these volumes was John Elliot, a native of Somersetshire, who practised medicine in Great Marlborough-street and Newman-street. He, like his more prosperous namesake, was crossed in love, and for having fired a pistol at the object of his affections was committed to Newgate, where he died in 1787. The publications in question have been before the world for more than a hundred years, and anything connected with the life and work of Dr. Fothergill must have commanded some attention. Mr. Bailey is therefore the more to be congratulated on his sagacity, and literary men of a bibliographical turn will easily understand the satisfaction he must have felt in tracing out the successive steps of the correction which he has presented so clearly.

MEDICAL MEN AND TRADE IN ARTICLES OF FOOD.

YET another question in the ethics of medical men in relation to limited companies. They may receive—as some of our correspondents have—a circular from the managing director of such a company urging them to take first mortgage debentures which pay 6 per cent. per annum. So far so good. But the debentures will also give the holders a strong inducement to promote the sale of the particular articles by which they are to realise this high interest. The circular states as a fact that the debentures are held largely by medical men. This is a vague expression. We should be sorry to think that any considerable number of medical men had put themselves into what we consider an undignified and somewhat tied position. At any rate, for the sake of those who have not so committed themselves we venture to discuss the point and to discourage such investments. The preparations may be as good as the managing director represents. They may have all the dietetic virtues of meat and wine, of stout and champagne. But it is not for medical men to have commercial interests in a commercial monopoly of the dietetic class, on the merits of which they should have a perfectly open mind. They should be so free from interest in it as to be under no inducement to order it other than arises from its scientific claims. We cannot see that the debenture holders in this company are so free. They trade in articles which, however good to-day, may be surpassed to-morrow. To tempt medical men by direct appeals and a high rate of interest to buy debentures is not very commendable in the managing director.

PHYSICAL TRAINING IN BOARD SCHOOLS.

WE have so often had occasion to rebuke the School Board of late that it was with a feeling of relief we read the account of the Physical Training Exhibition at the Albert Hall. Competitions were held in military drill and other physical exercises, together with the interesting display by blind School Board children trained at the Normal College for the Blind. The Duke and Duchess of York were present, and her Royal Highness presented the prizes. There can be but one opinion as

Digitized by Google

to the value of instruction and training in physical exercises, and until quite lately England was sadly behind every other country in the provision made for education of this kind. Of course the upper classes and the members of the army and navy received more or less physical training, but there was nothing like the systematised instruction which exists now, and even that lags behind the training given to the youth of both ancient Greece and Rome. Having succeeded so well in this branch of education the School Board had better give up teaching physiology and the other "ologies" and devote its attention to teaching children to swim. We do not hesitate to say that the money squandered since 1871 upon insanitary buildings, and upon equally useless subjects of instruction, would have provided plenty of baths; and the sooner the board realise this fact and eliminate at least a third of the subjects they teach the better.

MEDICAL FEES AT PETTY SESSIONS.

AT the Farnham Petty Sessions on the 11th inst. a man named Claytonhill was brought up in custody from the Farnham Workhouse charged with attempting to commit suicide. The case presented no unusual features beyond the injustice to which Dr. Scott, the medical man subpœnaed, was subjected. Dr. Scott, acting on his summons, attended the court, a distance of ten miles from his home. Not only was he compelled to leave his private professional work, but in addition had to pay his travelling expenses. Moreover, he was expected to give evidence without any fee or remuneration whatever. The clerk of the court said that the justices had no power to allow Dr. Scott's expenses unless the case was sent for trial. The magistrates agreed that it was a great hardship to Dr. Scott, but that they were helpless in the matter. Under these circumstances Dr. Scott had to choose whether he would give evidence on the chance of being paid if the prisoner was committed, or decline to be sworn without a guarantee that he would receive a fee for his services. He adopted the latter alternative, whereupon the bench, who were in full sympathy with Dr. Scott, directed that a note of his refusal to testify should be taken. The chairman quite agreed that "the sooner the law was altered the better it would be for justice." It is difficult to realise that the law should be so harsh and defective as to order or even sanction that a medical man should be compelled to attend on a subpœna, and that on being sworn he must give evidence without other surety of remuneration than the contingency of the accused being committed for trial. We must admit that we were ignorant that such a state of things obtained, for in the police courts of the metropolis a medical man is paid according to a scale sanctioned by the Home Secretary for his attendance, independently of the issue of the magisterial investigation. If the petty sessional justices have no equivalent powers the sooner they acquire them the better. A system that casts such an indignity and injustice on our profession is nothing short of a public scandal.

A SUPPLEMENTARY Charter, by warrant, under the Queen's sign-manual, has been granted to the University of Durham. This Charter enables Convocation to grant to women any degrees, excepting only degrees in divinity, which they have the power to grant to men. The degrees of the University of Durham in medicine, science, arts, literature, and music are, therefore, now obtainable by women.

THE Council of the Royal College of Surgeons of England has appointed a Committee to receive a deputation of the Members of the College regarding the proposed Amended Charter on Friday, July 26th, at 3 P.M.

WE are asked to state that a meeting of members of the profession who are opposed to the proposed Bill for the Registration of Midwives will be held at St. Martin's Town Hall, Charing-cross-road, London, W.C. (small hall), on Monday, July 29th, at nine o'clock P.M. (the night before the annual meeting of the British Medical Association).

THE Dental Hospital of London will give a conversazione at the Royal Institute Galleries, Prince's Hall, Piccadilly, on Thursday, July 25th. At 8 P.M. there will be a reception by the staff of the hospital, and later Sir William MacCormac will distribute the prizes.

THE Members of the British Medical Association are invited to visit Guy's Hospital on Friday, Aug. 2nd, between 3 and 6 P.M. Cases of interest will be exhibited and tea provided.

WE are very glad to be able to inform the profession that Dr. M. Armand Ruffer, the director of the British Institute of Preventive Medicine, has made a good recovery from his recent illness.

Pharmacology and Therapeutics.

ITROSYL—STANDARD CONCENTRATED NITROUS ETHER FOR MAKING NITROUS ETHER OF B.P. STRENGTH.

To the practitioner there is probably nothing more uncertain in the whole range of the Pharmacopœia than the composition of spiritus etheris nitrosi. Its common drawback, as is well known, is its instability, leading to an excess of acid and a deficiency in the quantity of real nitrite of ethyl. Yet in view of its undoubted value in therapeutics, how important is it that it should be of uniform and standard strength. We recognise, therefore, a departure of more than ordinary importance and value in the introduction by Messrs. Fletcher, Fletcher and Co., of Holloway, of a concentrated form of nitrous ether, which, with spirit, can be diluted at will, or to the maximum strength of the British Pharmacopœia. One ounce of Itrosyl contained in twenty ounces of rectified spirit forms, we find, a spirit fully in accordance with the requirements of the Pharmacopœia. The concentrated ether is supplied for the first time by Messrs. Fletcher in hermetically sealed glass "cartridges," which, moreover, are impervious to the action of light. Each tube contains one fluid ounce of a strength which cannot alter, since there can be no loss by leakage or evaporation, and by the use of amber-coloured glass no change by the action of light can take place. Apart from the fact that the practitioner can thus be provided with a well-known unstable drug in a permanent and reliable form, it admits also of transportation into those climates where alteration in composition is especially liable to occur. In a word, Messrs. Fletcher and Co. have taken all the precautions it is possible to take to afford the practitioner one of the most valuable drugs at his disposal which shall be of a reliable and unfailing strength.

THYROID POWDER IN PALATINOIDS.

The value of the protective influence of the palatinoid in preserving many of the organic extracts and presenting them in an undeteriorated condition is brought into further prominence as this line of treatment advances. We have recently received some palatinoids from Messrs. Oppenheimer, of 14, Worship-street, Finsbury-square, each containing thyroid powder equivalent to one-tenth of a grain of the fresh thymus gland. As with the other animal extracts

Digitized by Google

now used so largely in the treatment of disease—as, for instance, pituitary and supra-renal extracts—the jujube cover of the palatinoid acts as a hermetic seal against the decomposing influences engendered by exposure to the air, added to which the palatinoid is obviously a convenient form for the administration of these therapeutic agents.

THYROID TREATMENT OF GOITRE.

Professor Kocher of Bern has communicated to the *Correspondenzblatt für Schweizer Aerzte* his experience of the treatment of goitre by means of thyroid administration. The effect is unmistakable, he says, the swellings becoming distinctly smaller. Symptoms of suffocation may be abolished by the treatment in consequence of the diminution in size of the goitre, but in no case did the swelling entirely disappear. Only in three cases was the treatment unsuccessful, and one of these was that of a large cystic goitre in which success could scarcely be looked for; but in spite of this success Professor Kocher utters a warning against too sanguine views as to the success of thyroid treatment of goitre and expresses the opinion that this mode of treatment is not more efficacious than that by iodine. Success is only to be expected if the treatment is undertaken at the right time and is carried out with energy and patience.

BENZO-NAPHTHOL IN TROPICAL DYSENTERY.

Benzo-naphthol has been employed by Dr. José A. Clark in an epidemic of dysentery which occurred in Alquizar, Cuba, and during which he had 137 cases of the disease under treatment; of these he considered 23 as serious and 114 as of a mild type. The mortality amongst those treated with ipecacuanha and calomel, opium, &c. amounted to 9 per cent., while that amongst those treated by benzo-naphthol was scarcely more than 2 per cent. This drug had the great advantage over the more usual ones of not causing vomiting, salivation, or depression of the circulation, and it also brought patients through the attack more rapidly. Forty-five grains per diem were given to adults and but little less to children.

HYPODERMIC INJECTIONS OF CARBOLIC ACID IN TETANUS.

By means of a series of subcutaneous injections of carbolic acid Dr. Osherovski has successfully treated an apparently hopeless case of tetanus. The patient was a man who had a gunshot wound in his left leg, which was followed ten days later by tetanus, commencing in the muscles of the lower jaw and going on to general spasmodic contractions. Morphia, opium, and chloral in large doses were given without any effect, the spasmodic seizures only becoming more frequent and more severe. After the tetanus had lasted for ten days subcutaneous injections of carbolic acid of the strength of 2 per cent. were tried, twelve drops being injected every three hours. After two days of this treatment a marked improvement manifested itself, the spasmodic attacks becoming less violent and the respiration more easy. The injections were continued until twenty-eight had been given, and a few days later the patient was discharged completely recovered.

FORMOL AS A DISINFECTANT.

As a substitute for sulphurous acid, now commonly used in the disinfection of rooms and articles of wearing apparel after the occurrence of infectious disease, MM. Berlioz and Trillat some time ago proposed the use of formol or formaldehyde, and M. Bardet has recently undertaken a series of experiments in conjunction with M. Trillat which appear to show that the substance in question when prepared in considerable quantity and disengaged in a room, or even in one of the rooms of a house where all the internal doors are open, is a perfectly safe and efficacious disinfectant. They found that by the use of an apparatus converting one litre of methylic alcohol into formol per hour for six hours a set of rooms with a capacity of 300 cubic metres could be absolutely disinfected, and this without the slightest deleterious effect upon furniture or other articles contained in the rooms, a few hours' ventilation being sufficient to restore all the contents of the rooms to their original condition. The experiments were conducted by means of injecting animals with cultures obtained from pieces of woollen, cotton, or other fabric which had been previously impregnated with various forms of virus and then subjected to the action of formol after various periods.

THE PARIS SANITARY CONGRESS.

(FROM A SPECIAL CORRESPONDENT.)

Money Value of Household Refuse.—Sanitation in Private Thoroughfares.—New Method of Pneumatic Drainage.—Certified Plumbers.—Width of Streets.—Cheap Dwellings. The Liernur System.—Warming Houses.—Hot Walls and Cold Air.—Testing Chimneys.

THE first practical question discussed by the Congress related to the disposal of domestic refuse, the contents of dustbins, &c. M. Petsché, engineer, presented a report on the subject, in which he pointed out that the domestic refuse of the Parisian houses contained per ton 3 to 5 kilogrammes of nitrogenous substances, worth from 4*s.* to 6*s.*; 3 to 5 kilogrammes of phosphoric acid, worth from 9*d.* to 1*s.* 3*d.*; 2 to 4 kilogrammes of potash, worth from 8*d.* to 1*s.* 4*d.*; and some 30 to 40 kilogrammes of lime, worth from 3*d.* to 5*d.* Roughly speaking, the value of a ton of refuse might be estimated at 6*s.* to 9*s.* Consequently the domestic refuse of the Parisian houses is, theoretically speaking, worth about £200,000 per annum! Yet the Parisian contractors sell this refuse, delivered on a railway truck, for 8*d.* to 1*s.* 3*d.* the ton; the maximum charge for transit on the railways is from 2*s.* to 2*s.* 5*d.*, so that by the time it is placed on a field as manure it costs from 2*s.* 8*d.* to 3*s.* 8*d.* The utilisation of this refuse for agricultural purposes may, therefore, be expected to increase; but the question arises whether public health may not be endangered by transporting to different parts of the country refuse that may be at times infected. M. Petsché then described at length the various destructors employed in America, England, &c. M. de Montricher, who has succeeded in fertilising some of the arid, stony plains of The Crau with the refuse brought from Marseilles, explained that the refuse was loaded on the railway trucks at night at a special depôt away from inhabitants and nowhere near to passenger stations. Some discussion ensued concerning the storing of refuse in the kitchens of houses let out in flats; and M. Bechmann, engineer of the town of Paris, proposed and the Congress adopted a resolution in favour of encouraging the building of shafts down which refuse from all the kitchens in a house could be thrown so as not to remain in the apartment. Some doubts were expressed as to whether such shafts could be kept clean and would not cause a nuisance. Such shafts already exist in many of the flats in Victoria-street, London. Unfortunately, Mr. Tidman, sanitary inspector for the Westminster district, was not present at this sitting of the Congress, and therefore no evidence could be adduced as to how the system works. The question is, however, important, for in large towns the number of houses built as flats is yearly increasing, and in such houses dustbins in the yard or garden are not readily accessible. The Congress passed a series of resolutions to the effect that domestic refuse should be collected every morning and conveyed in metallic and closed receptacles that could be easily disinfected; that to utilise such refuse for agricultural purposes the railway companies should lower their tariffs and establish special isolated depôts for loading the refuse into railway trucks; finally, that the destruction of such refuse by fire was a satisfactory solution of the difficulty from the health point of view if the temperature was sufficiently high and of long duration, but that further researches should be made so as to utilise the heat and the products of the combustion.

The question of private roads was next taken in hand, and it proved a very thorny matter. The Mayor of Marseilles explained that in his town there were many places that to all intents and purposes were public thoroughfares, but which he could not control or even inspect because they were, legally speaking, private property. The Congress ultimately voted a resolution to the effect that all roads that did not belong to a town or commune, but which were frequented by the public or inhabited by different individuals, should be subjected to the same regulations, inspection &c. as governed public thoroughfares.

During an afternoon unofficial sitting M. Chardon, engineer, described the pneumatic system of drainage applied to the Levallois-Perret district, which is a modification of the well-known Berlier system. He pointed out that all the gases from the drainage-pipe in which the vacuum

Digitized by Google

was produced were burnt in passing through the furnace of his boilers. Thus, the vexed question of ventilation for sewers was avoided and the foul air sterilised. He did not pretend that the application, as made at Levallois-Perret, was perfect. The house drains were foul because the district was poor and employed little or no water; but they had at least abolished the abomination of cesspools. They removed the sewage from the houses without fouling the sewers and prevented all escape of sewer gas. The members of the Congress visited the works at Levallois-Perret and were able to see for themselves that no nuisance was produced. They were shown an ingenious method by which a vacuum could be produced in the receiving tanks by means of a steam jet which had cost £32, and did the same work as engines which had cost £1600. This invention will greatly reduce the cost of drainage by pneumatic suction.

The Congress in the morning and official sittings discussed at great length the building and draining of houses. M. A. de Baudot, Government architect, urged that architects had not progressed with the age; that they built houses as they used to build a century or more ago; that while they made thick, handsome street frontages, the walls at the back of the houses were flimsy and of insufficient protection for the inhabitants. Damp and uneven temperature resulted. M. George, architect, read a lengthy paper on house drains, concluding by proposing a series of resolutions in favour of trapping and ventilation, soil and other pipes, according to the principles well known and generally adopted in England. The only new point was a clause in the resolutions insisting that all traps and water-waste preventers or flushing cisterns should be surrounded with some non-conducting substance, so as to protect them from the frost. A good deal was said in the course of the discussion as to the necessity of enforcing the examination of, and giving diplomas to, sanitary plumbers. Mr. Tidman, secretary of the British Sanitary Inspectors Association, pointed out that in England sanitary inspectors received their diplomas from the British Sanitary Institute, and that the Plumbers' Company sent examiners all over the country to examine both in theory and in practice intending sanitary plumbers. He hoped the time would come when no plumber would be allowed to work at drains unless he possessed a diploma showing that he was fully qualified. M. Masson, sanitary inspector for Paris, explained that two schools of sanitary plumbing had been established in Paris which gave brevets of competence, after three years' training, to those who satisfactorily passed the examinations. The Congress finally adopted a resolution to the effect that such schools of plumbing should be encouraged and that certificates of competence, after examinations, should be given to working men plumbers.

The question which incidentally came forward as to the width of streets in comparison with the height of the houses elicited from M. Charles Lucas, secretary of the Architects' Central Mutual Defence Fund, a somewhat curious statement. He remarked that, as hygienists, they would be constantly tempted to vote in favour of what, as architects, they would have to combat. If a resolution proposed an ideal the majority would not vote for what as hygienists they considered as most excellent. Mr. Adolphe Smith argued that hygiene was a profession in itself. A hygienist must know something of medicine, of chemistry, of engineering, of architecture, of plumbing, and other handicrafts. They had not to consider any special professional interest or what was expedient or practical in any one particular locality, but to lay down the principle which all localities would try to realise when practicable. He thought that in this case the principle was that the direct rays of the sun should be able to reach once in the day the windows of all habitations. M. Bechmann, chief engineer of the town of Paris, protested that such a rule did not apply to tropical climates and that they were not going to pull down all Paris because of the vote of a Congress. M. E. Cacheux, engineer and administrator of the Society for the Creation of Cheap Dwellings, who read a paper on the drainage of such dwellings, also argued in favour of the direct rays of the sunlight for all inhabited rooms. Nevertheless, the Congress refused to pronounce an opinion on this point, the ideal of the hygienists evidently being thought impracticable.

M. Morin-Goustiaux, vice-president of the Government Commission on the Unwholesome Dwellings of Paris, read a paper on the necessity of an efficacious control of the sanitary appliances &c. in private dwellings. He quoted American State laws on the subject, and concluded by presenting resolutions demanding that the rules relating to plumbing work should be as uniform as possible in all towns, that all plans for drainage should be submitted to a competent authority, and no drains covered over till they had been verified and inspected and the various apparatus employed tested. M. Masson having stated that this was already done in Paris these resolutions were adopted. M. Charles Lucas brought forward a series of resolutions on cheap artisans' dwellings, demanding that in planning out such buildings greater attention should be paid to the direction of the most frequent winds; that the employment of non-conducting substances should become more general, especially for walls which, from motives of economy, had to be made very thin; that the disposition of the rooms should be such as to enable the mother to watch over her little children while attending to her ordinary domestic duties; that the walls, to admit of frequent washing, should be painted rather than papered; and that the corners should be rounded off so as to present no angles for the accumulation of dirt and vermin. All these recommendations were approved by vote.

A resolution urging that the Sanitary Bill adopted by the Chamber of Deputies, and now before the Senate, should become law at the earliest possible date was unanimously adopted; and to facilitate the creation in all localities of competent sanitary authorities, a chair of hygiene should be established in all schools of architecture. M. Jeannot explained what great service the Bureau d'Hygiene of Besançon had rendered, though its income only amounted to £28 per annum. Mr. A. Smith and M. Desmenard (general secretary of the Congress) both energetically protested that this meant work done gratuitously in their lecture hours by the medical men and the engineers who constituted such bureaux, and that none but a clerk or an office boy were paid for their services. This was not the way to bring about the sanitary reform of the country. Sanitary officials must be paid sufficiently to be able to devote their best energies to the great mission they had to fulfil.

A considerable number of papers were read in the afternoons on new inventions, such as a mask for protecting workmen from injurious dust, by Dr. Detourbe; a new method of purifying river water by propelling fresh air through the water, which was suggested by M. Robert, engineer; a system of closet pans, suggested by Dr. Châtelin, which, while offering a partial seat or rest, compelled those using the closets to assume a position in keeping with the laws of anatomy. Dr. Châtelin argued that the ordinary seat had injurious effects and created a predisposition to hernia. The spine and hips should describe an acute and not a right angle. M. de Montricher described how he had proposed to utilise large and badly constructed sewers by placing in them small and well-built sewers which would only overflow into the larger sewers when there was a heavy rainfall. Finally, Mr. Sijmons, engineer from Amsterdam, and Mr. Liernur both explained the working of the Liernur system. The latter gentlemen, however, persisted in showing that their system, as worked at Amsterdam, produced a handsome profit. It was easily shown that this profit was due to the fact that the population thus drained only yielded 2 litres per head per day of sewage and slop water. Under such circumstances the soil pipes could not be flushed, and must remain in a permanent state of filth. They claimed that they had apparatus with which they could evaporate and dry 36 litres of sewage by the consumption of 1 kilogramme of coal, but confessed that they did not raise the heat of the sewage to 100° C. How, then, was the sewage sterilised? Doubtless, under special circumstances pneumatic suction may prove a very useful motive power for drainage purposes, but as applied to the town of Amsterdam it certainly did not appear to meet with the approval of the great majority of members of the Congress. At the same time it may be admitted that, whether by suction or by propulsion, pneumatic power greatly facilitated the application of the separate system, which, it was pointed out, was becoming more and more popular in England. Two facts had helped more particularly to create the reaction in favour of the separate system. The density of population had rendered the disposal of sewage almost an impossibility. The combined system, by mixing the rainfall with the sewage, greatly added to the difficulty. With the separate system the quantity and quality of the sewage could be very accurately estimated; and whatever the condition of the weather it did not vary. It was therefore more easily treated. Secondly, we now strove to have self-cleansing sewers. But for a sewer to be self-cleansing it must be at least half filled once a day and have a sufficient fall to ensure that the water would

Digitized by Google

travel at a velocity of 760 millimetres per second. If the sewer was large enough to take rain water it was impossible to obtain these conditions. Again, to obtain a sufficient fall to ensure this self-cleansing velocity it would be necessary to raise the sewage in a great number of different places, and the raising of rain water increased the cost twentyfold. M. Masson urged that the rain water, which had washed the streets of a town, was as foul as sewage proper, and should therefore be treated as such. The discussion on the Liernur system of drainage, though very animated, did not lead to the proposal or adoption of any resolution.

Another very interesting discussion was held on the warming and ventilation of dwellings. M. Ch. A. Gautier, president of the Society of Architects holding the Government diploma, read a paper on the subject. He denounced chimneys as warming badly; objected to the looking-glass placed on the mantelpiece as checking the heat that might otherwise come from the wall; found that stoves were unwholesome and sometimes dangerous; and proposed the warming of dwellings by steam coils in the walls of the rooms. M. Emile Trélat had here an excellent opportunity to bring forward his well-known theories on the subject, and it was gratifying to note how well these theories were appreciated and understood by all present. Everybody agreed with him that warming should be by radiation and not by convection. It was the walls, the floor, the ceiling, and the furniture that should radiate heat on the persons within, but the air should not be warmed; it should, on the contrary, be as cold as possible. Differences of opinion only arose when M. Émile Trélat urged that even unwholesome dried air or a portable stove might be employed to heat a room so long as no one was in the room; then the stove should be removed or the supply of dry, hot air cut off, the windows thrown open, and kept open while anyone was in the room. Some members of the Congress thought that traces of carbon monoxide might still remain in the room even when the windows were wide open. Many argued that the nearest approach to M. Trélat's ideal was the placing of hot steam pipes in the walls and the ample opening of windows. A great deal was said about the injury done by stoves, notably to people who lived in apartments above, and who suffered from the defective construction of chimneys. A resolution was passed that chimneys, before they are used, should be tested by the authorities in the same manner as soil-pipes are tested to see that there is no leakage. This was, perhaps, one of the most original and practical suggestions made during the whole of the Congress.

Such, briefly, are some of the main subjects discussed at the Congress during the course of the week. It must be confessed that some of the architects and engineers present showed that they had only just commenced to study sanitary questions. Several of the speeches were but lame reproductions of what had been said at previous congresses. This, however, was to be expected. The Congress was more disappointing in so far as the engineers and architects did not bring forward as many plans and projects for the practical application of sanitary principles as had been anticipated. Nevertheless, the Organising Committee and M. Desmenard, its energetic secretary, are to be congratulated on having grouped together some 300 persons in a congress, particularly as most of the members were architects and engineers, and there were, comparatively speaking, but few medical men and old tried sanitary reformers. So it may be said that new ground has been opened up, that a new class of sanitary reformers have come forward, and all this will help in the good cause.

Paris, July 15th.

YAWS OR FRAMBŒSIA.[1]

THIS large and voluminous blue-book, consisting of 368 pages and illustrated by numerous coloured plates and drawings, is an exhaustive contribution by Dr. H. A. Alford Nicholls, the Special Commissioner selected by the Secretary of State to conduct an investigation and furnish a report to the Colonial Office on the subject of which it treats. Dr. Nicholls in describing the nature and scope of his inquiry alludes to the fact that he had received a communication from the late Sir George Buchanan, the medical officer of the Local Government Board, containing suggestions as to certain matters relating to the investigation and the line of action to be followed. The question is one of great importance in those tropical countries in which the disease prevails, and the facts which Dr. Nicholls has been fortunate enough to make public are not only of interest in themselves, but they tend to throw a new light upon the subject and to call for a reconsideration of the theories respecting it which have been put forward by previous writers. Dr. Nicholls is of opinion that the great obstacle to the successful treatment of the disease in its different types has been the ignorance which has hitherto prevailed about its pathology. He has therefore set himself to work this out in order to place its treatment on a proper scientific basis.

It would be impossible within any reasonable compass to consider the large mass of material which accumulated in Dr. Nicholls's hands during the course of his mission to the various islands. The consideration which he has bestowed upon its arangement and analysis will no doubt prove of value in the way of reference to future inquirers, but the material is still very voluminous and not easily condensed for the purposes of a review. The disease known as yaws or frambœsia was, he tells us, unquestionably introduced into the West Indies by negroes brought from the coasts of Africa as slaves; indeed, some of the older West Indian medical writers mention the fact of negroes suffering from yaws being landed from slave ships from Guinea. But there is no definite information obtainable, in regard to each island, as to whether the spread of the disease among the slaves on the plantations was due to the direct importation of affected persons from Africa or to an introduction and spread of the infection from a neighbouring colony. Yaws is the name that has been applied to the disease by the English from the time of the slave trade. The name "frambœsia" was constructed by Sauvages in 1761 to designate the cutaneous tumours which, when divested of their crusts, were considered to resemble raspberries. The French word *framboise* was Latinised into frambœsia. Several other names have also been given to the malady. Dr. Nicholls considers that the Celtic word *ias*, pronounced *yas*, and meaning heat, boiling or bubbling up, is the source of the English derivation of yaws. His experience teaches him, he says, that yaws is not a cachectic, impetiginous, or an exanthematous disease, but that it properly belongs to the group which the late Dr. Tilbury Fox called the diathetic diseases, and is to be included in the same category as scrofula, syphilis, and leprosy. It is not simply a local cutaneous affection, but seems to be a general disease, of which the eruption is only the local manifestation. The mistaken belief of so many authors that yaws is identical with syphilis has caused the question of the origin of the two diseases to be brought into a state of confusion. The considerations of this matter, in view of disentangling the difficulties surrounding the origin of yaws and of those connected with the geographical distribution of the disease, are well worked out by Dr. Nicholls. Yaws prevails throughout the tropics of the New World. It is found in various parts of South America and Central America, and is especially prevalent in the West Indies and in Brazil—in fact, in those countries of tropical America to which most of the African slaves went. It is said to exist in all parts of tropical Africa, but the west coast appears to be its endemic focus. The African islands off Mozambique, including Madagascar, are also reported to be infected, and naturally cases are occasionally met with in the northern countries bordering on the Mediterranean. There does not seem to be any conclusive evidence, however, that it prevails in any Asiatic country. For a description of the symptoms of the disease our readers cannot do better than refer to Dr. Nicholls' report, to the plates illustrating its local features and manifestations, and the narrative of cases given by him and others. Without doubt one of the most important and disastrous complications of yaws is syphilis. When yaws and syphilis occur as intercurrent affections very destructive ulcerations may ensue. Mercury is necessary for the treatment of the syphilis, but its effect is very prejudicial in yaws.

Dr. Nicholls and Mr. Francis Watts, the Government chemist of Antigua, performed a good deal of pathological and bacteriological work together at the Chemical Laboratory in Antigua in connexion with this inquiry; and with the

[1] Report on Yaws in Tobago, Grenada, St. Vincent, St. Lucia, and the Leeward Islands, addressed to the Right Honourable Lord Knutsford, G.C.M.G., H.M.'s Principal Secretary of State for the Colonies, by H. A. Alford Nicholls, M.D., F.L.S. London: Printed for Her Majesty's Stationery Office. 1894.

Digitized by Google

aid of scientific apparatus from England Dr. Nicholls was able to carry on and complete these investigations on his subsequent return to Dominica. Some of the results of these researches are summed up as follows :—

"A microbe in the form of a micrococcus was found constantly in the secretion from the granulomata characteristic of yaws, which was successfully cultivated in nutrient media, and pure cultures were obtained to the third generation. The microbe was discovered in abundance in the affected tissues of persons suffering from the disease, and no other pathogenic microbe was found in association with it. In no instance was this micro-organism discovered in the blood, although it was successfully multiplied in the serum in drop cultures. It was found and successfully cultivated in Antigua, St. Kitts, and Dominica, and under identical conditions in these three islands. Pure cultivations of the micrococcus of yaws showed that its microscopical characters were constant, and that its macroscopical appearances differed from those of micrococci already discovered and described in various works on bacteriology. The lower animals are probably immune, inoculations giving negative results, as did also the inoculations from the secretions of the granulomata. In the absence of the concluding proofs of the pathogenesis of the microbe—viz, the production of the disease in healthy animals by inoculation of pure cultivations and the after discovery of the micro-organism in the fluids or tissues—it cannot yet be positively declared that the micrococcus is the contagium of the disease. But Dr. Nicholls and Mr. Watts, in view of the attributes of the disease being clearly indicative of its origin and causal connexion with a microbe, and of the fact that they were able to establish that a micrococcus is its constant accompaniment, as well as of the subsequent discovery by Dr. Nicholls of the microbe in the lymphatic system and in various organs of a patient who died from yaws, consider themselves justified in inferring that the micrococcus is nevertheless the cause of the disease and that it invades the system through the lymphatics. It is important to observe, in connexion with the bearing it has on the mode of propagation of this malady, that the micro-organism has been found in the dust on the floor of rooms in which yaws patients have been living, and that, as a matter of experiment, it is capable of retaining its vitality of growth and multiplication for a considerable time. The clinging of the contagion to certain huts and localities, and the occurrence of a sudden outbreak of the disease when the heavy rains of a tropical climate moisten the earthen floors are therefore capable of explanation.

We have said enough to show that the results of the latest investigations, if ratified by subsequent researches, are likely to throw a new light upon the subject of yaws, and to call for a reconsideration of the views that have been previously held in respect to it. We may usefully conclude this article by referring our readers to one that appeared in THE LANCET of June 21st, 1873, on the disease in question.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE WEBER-PARKES PRIZE AND MEDALS.

WE have received from Dr. Edward Liveing, the Registrar of the College, the following particulars respecting Dr. Hermann Weber's Prize Foundation in the College, and have pleasure in calling the attention of the profession to them.

The prize is of the value of £150 or thereabouts, and will be awarded triennially to the author of the best essay upon some branch of the subject of Tuberculosis, especially with reference to pulmonary consumption in man. The first award will be made in 1897, and the adjudicators have selected as the subject for the essay "The Means, Prophylactic or Curative, deemed by the author to have value in the control of Tuberculosis, especial regard being had to their application to Human Tuberculosis." This subject was selected by Dr. J. E. Pollock, Dr. Thorne Thorne, and Professor W. S. Greenfield, who were nominated by the President of the College, and these gentlemen will have the onus of adjudicating between the essays. The essay must be based on original work and observations (experimental or other) of the author, and must include a detailed exposition of the methods employed and their mode of application.

The following are the full regulations for the guidance of intending competitors :—

THE WEBER-PARKES PRIZE AND MEDALS.

Regulations.

1. That the prize founded by Dr. Hermann Weber, in memory of the late E. A. Parkes, M.D., be termed the "Weber-Parkes" Prize.
2. That the prize be awarded triennially to the writer of the best essay upon some subject connected with the etiology, prevention, pathology, or treatment of tuberculosis, especially with reference to pulmonary consumption in man; that in making the award the College have regard to careful collection of facts and original research.
3. That the value of the prize be 150 guineas, or such sum as the interest accrued on the capital, after payment of expenses, will permit.
4. That a bronze medal be awarded to the holder of the prize, and a similar medal, to be distinguished as the second medal, to the essayist who comes next in order of merit.
5. That an Adjudication Committee be nominated on each occasion by the President from among the Fellows of the College, and that it be the duty of such committee to select the particular subject for competition.
6. That the same committee which selects the subject shall adjudicate upon the essays sent in upon that subject, the President having power to fill up any vacancies which may have occurred meantime in the committee.
7. That the adjudication be made every three years at some time previous to St. Luke's Day, when the prize and medals will be presented to the winners.
8. If, in the opinion of the judges, no essays are presented of sufficient merit to deserve either the prize and first medal or the second medal respectively, that the College be at liberty, on the recommendation of the judges, to award either one or both to the author or authors of any original work or works on the subject produced within the preceding three years which may be deemed worthy of the same; and in the absence of such work or works that the corresponding award or awards be not made, and the sum assigned for the same be added to the capital amount.
9. That the subject for the next ensuing competition be selected and advertised within a period of three months from the last presentation; or, failing any award, from the day on which the prize would have been presented had an award been made; and that the competing essays be delivered to the Registrar on or before July 1st in the year of the award.
10. That the competition be open to members of the medical profession in all countries. The essays to be typewritten and in English; or if written in a foreign language to be accompanied by a translation into English.
11. That each essay bear a motto, selected by the writer, who shall insert his name within a sealed envelope having the motto on the cover, the envelope being transmitted with the essay to the Registrar, who shall return the unsuccessful essays to their authors.
12. That the prize essay become the property of the College, and that the College may grant its author permission to publish it if he so desire.
13. That the medals shall present on the obverse the bust of the founder; on the reverse a design relating to the prevention and treatment of pulmonary tuberculosis, with the inscription (exergue), "Prevention and Cure of Tuberculosis," and that the name of the recipient and the date of the award be placed on the edge of the medal.

THE CHEMICAL AND BACTERIOLOGICAL EXAMINATION OF DRINKING-WATER FROM THE STANDPOINT OF THE MEDICAL OFFICER OF HEALTH.

THAT there has within recent years been a decided change in the attitude of the medical officer of health towards the value to be attached to chemical analysis few will question, and it is perhaps a debatable point whether the reaction which has taken place in favour of the bacteriologist may not have led to a somewhat exaggerated importance being accorded to the results of the bacteriological examination of water. In former days the dictum of the chemist in regard to any given water was accepted as final, and the water stood condemned or absolved according to the results which the sample submitted yielded. At the present time the chemist has to some extent been superseded by the bacteriologist, and the dictum of the latter is now by some considered to be as conclusive as was that of the chemist in former days. Under these circumstances it is hardly to be wondered at that bacteriological methods should be subjected to some criticism at the hands of the chemist. To those who would seek to study the question from the chemist's standpoint we would commend an able article by Dr. Dupré, F.R.S., which appeared recently in the *Analyst*, and to those who, like ourselves, are approaching the subject from the standpoint of the medical officer of health we cannot do better than advise the perusal of a paper which appeared also in the *Analyst*, and which has now, together with Dr. Dupré's paper, been issued in pamphlet form. For the information of our readers we will,

Digitized by Google

in the first instance, refer briefly to one or two of the salient features of these papers, and in conclusion will offer a few remarks upon the main question.

Chemical analysis shows us, Dr. Dupré contends, in ninety-nine cases out of a hundred whether a water is polluted by sewage or not, more particularly so if the plan proposed by himself and Mr. Hehner be adopted of comparing the water under examination with one from the same district and formation, which the surroundings show to be unpolluted. This latter proviso seems to us a somewhat important concession from the chemist's standpoint, since it practically means that apart from a study of a water's environment chemical analysis may be misleading. As far, however, as we are aware this method adopted by Dr. Dupré is not a universal one among chemists. By the detection of pollution the chemist is able, Dr. Dupré urges, to anticipate danger, whereas the bacteriologist is only able to discover pathogenic organism after disease has already been caused; or, as he graphically expresses it, the chemist can close the stable door before the steed is stolen, the bacteriologist can only close it after the steed has gone. The answer to this argument is obvious, and Dr. Dupré, anticipating the bacteriologist's objection that in the bacillus coli he has as fine an index of pollution as the chemist, replies that chemical analysis stands condemned because it is unable to detect pathogenic organisms, and he infers that on this ground the chemist and bacteriologist must fight their battle. The estimation of a water's safety by reference to a numerical standard of micro-organism is a method for which Dr. Dupré has little sympathy. Are we to be told, he observes, that the deep-well water of the Kent Water Company is an admirable drinking-water as it comes from the well, and absolutely unfit for drinking one or two days afterwards? For the detection of unfiltered sewage biological examination takes, Dr. Dupré thinks, first rank; but it is, he maintains, not pollution such as this which either the chemist or the bacteriologist is, as a rule, called upon to detect. In the case, for instance, of a well water, many of the micro-organisms may have been separated by filtration through the soil and subsoil, and it is in cases such as these that Dr. Dupré would claim for the chemist an easy victory. Experiment with artificially polluted water where a little fæcal matter and no urine are added is not, he contends, a fair test, as the conditions thus established unduly favour the bacteriologist. The "conveniently small measure" adopted by bacteriologists for recording their results is also matter for Dr. Dupré's criticism. "How beautifully free from impurity," he says, "would most water, or even sewage, appear if we stated our analytical results in parts per cubic centimetre instead of parts per 100,000." And, again, "What would be thought of a man who, if he found no fish in, say, ten cubic feet of sea water, were to pronounce that there are no fish in the sea?" Chemical and bacteriological examination of water should, Dr. Dupré considers, be used in conjunction with one another, but if one only is available that one should be the chemical. This, briefly stated, is the chemist's view. Dr. Thresh's paper is one which should certainly be read by every medical officer of health. He refers in a most lucid manner to the difficulties which beset the medical officer of health in his endeavour to find suitable water-supplies for his district; and he quotes cases where both chemical and bacteriological examinations have failed to indicate danger where the physical surroundings of the water have demonstrated it, and conversely where chemical analysis condemned a water when the environment absolved it from suspicion. Dr. Thresh approaches the subject as a medical officer of health, but in stating the fact it is well to remember that he is also a distinguished chemist. Without unduly deprecating the value of chemical and bacteriological analysis, Dr. Thresh insists upon the paramount importance of the physical surroundings of a water's source. Our expectations with regard to the value of bacteriological analysis have, Dr. Thresh observes, not altogether been realised, and its results are as likely to mislead as are those of chemical analysis. The numerical standard of the bacteriologist he considers as "illogical as the old chemical standards; both depend upon quantity, whilst the real issue is quality."

We confess that Dr. Thresh's attitude is one with which we feel ourselves largely in accord. It seems to us that in selecting a water to be used for drinking purposes *negative* evidence—i.e., failure to find evidence of suspicion—whether it be afforded by the chemist or the bacteriologist, is of very little value. Roughly, the one or the other expert reports, from his point of view, on one day only out of the 365 which make up a year. On the other 364 days samples submitted to the one or the other expert might have elicited a very different statement of fact. This being so, it is clear that the physical circumstances of the water's source are all-important, since they are, within moderate limits at least, constant for all the 365 days of the year. On the other hand, still referring to the selection of a water for drinking purposes, *positive* evidence against it as afforded by a single testing of the chemist or the bacteriologist is not to be accepted as absolutely convicting the water. It may be that the particular water is liable to an occasional and fleeting pollution from a contaminating agency that is no essential condition of its physical circumstances; and again, therefore, a strict examination of the surrounding circumstances of that particular water might altogether modify the adverse judgment arrived at by the chemist or the bacteriologist. As regards a water suspected of having caused epidemic disease just the same difficulty arises as to the value of *negative* evidence, whether chemical or bacteriological. In nineteen cases out of twenty neither chemist nor bacteriologist can speak of the water as it was at the time it was causing disease; and here again, therefore, the risk of specific pollution as evidenced by the surroundings is the all-important factor.

EVASIONS OF THE ADULTERATION ACTS.

WHILE it is impossible to withhold all sympathy for the retail dealer who has brought a conviction on himself by neglecting to use "reasonable diligence," we have none for the man who exercises his utmost ingenuity to deceive. The Sale of Food and Drugs Act legalises the sale of mixtures of chicory with coffee, and of margarine with butter, or alone, provided that the seller gives with it "a legible label" to that effect, the practice of taking the sample from a mass so labelled not being sufficient, since it is impossible to ensure the latter being in full view of the purchaser. But in any case the word "legible" is, like all relative terms, unsatisfactory—legibility depending on each person's acuity of vision, on the amount of light, and on the position and arrangement of the lettering. It is not at all unusual to find the qualifying words printed in the smallest type, or placed obliquely in a remote part of the label with the evident intention that they shall be unobserved. If the clause be more than a fiction or formality, the words which show that "things are not what they seem" should be as large and conspicuous as those which, taken by themselves, would convey a false impression—in fact, would be untrue. Mr. C. M. Atkinson, stipendiary magistrate at Leeds, ably argued the question, not of intent to defraud but of the sufficiency of such a label in a case in which a "purchaser" asking simply for "cheese," and pointing to a piece on the counter, was served with three pounds cut from it without a word of explanation. The label on the mass was "Valleyfield (finest oleine) Cheese," in three lines, the words "finest oleine" being in small, the others in capital letters; and the magistrate maintained that the words "oleine" and "cheese" should have been equally legible, if not combined in one. We might add that the word "oleine" does not either scientifically or technically meet the requirements of the Act, for oleine is a normal constituent of butter fat, and the legal description of these added fats is "margarine." The public have learnt the purport of the word; but in the case in question the purchaser, a labourer acting under the direction of the inspector, read the word on the label as "Curline," and was naturally unable to attach any meaning to it. Nor would he, as the magistrate remarked, have been much wiser if he had read it correctly, and, as he himself had done, found it defined in a dictionary as "the thin oily part of fat." It conveys no suggestion of the addition of foreign matter, whereas "margarine," having been discarded from scientific nomenclature, has been happily appropriated by the Act as a designation for all such artificial mixtures of extraneous fats. The Sale of Food and Drugs Act has now been in force for twenty years, and must be submitted to revision. Not only

Digitized by Google

should the qualifying words be connected with those they qualify and equally *legible*, but they should be equally *intelligible*. "Mixed" and "prepared" do not by themselves sufficiently indicate the nature of the process—the removal of a portion of the fat and of the woody fibre to make a fine soluble cocoa being no less a "preparation" than the addition of equal weights of brown sugar and potato starch.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on the 11th inst., the President, Mr. Christopher Heath, being in the chair. The President reported the result of the election of members of the Council, as given in THE LANCET of July 6th; and Mr. Alfred Willett, Mr. Treves, Mr. Butlin, Mr. Alfred Cooper, and Dr. Ward Cousins were introduced, and made a declaration in the terms of the oath prescribed by the Charter of 1800, and took their seats as members of the Council.

A recommendation by the Museum Committee was adopted, to the effect that the skeleton of a Diornis Maximus be purchased from the Canterbury Museum, Christchurch, New Zealand, for £70, and that Mr. Barlow of the Natural History Museum be employed to set up the skeleton.

The gift by Miss Greenhill of several volumes in MS. of a lexicon of Greek medical terms, compiled by the late Dr. Greenhill of Hastings, was accepted with the best thanks of the Council.

The President reported the half-yearly meeting of Fellows on the 4th inst., at which forty-five Fellows, including fourteen members of the Council, had attended, but that as no notices of motions had been given for the meeting no discussion of any kind took place.

The Council proceeded to elect two members of the Board of Examiners in Dental Surgery, Mr. Barrett being re-elected and Mr. Frederick Canton being elected.

The Council directed that the annual calendar should be completed to this date, and that the usual number of copies thereof be printed and offered for sale at 1*s.* per copy.

The following statement of attendance of members of Council during the past collegiate year was read:—

(Eleven meetings of the Council in the year.)

Name.	Meetings attended.
Sir T. Spencer Wells, Bart.	9
Mr. Jonathan Hutchinson	9
Mr. Wm. Cadge	10
Mr. Thomas Bryant	11
Mr. Thomas Smith	11
Mr. J. W. Hulke (died after seventh meeting)...	7
Mr. Christopher Heath, President	11
Sir William Mac Cormac	10
Mr. A. E. Durham (died after ninth meeting) ...	8
Mr. N. C. Macnamara	11
Mr. Oliver Pemberton	9
Mr. Reginald Harrison, Vice-President	11
Mr. Alfred Willett, Vice-President	11
Mr. T. Pickering Pick	10
Mr. H. G. Howse	11
Mr. John Langton	11
Mr. W. Mitchell Banks	9
Mr. W. Rivington	11
Mr. T. R. Jessop	9
Mr. F. Howard Marsh	11
Mr. J. Tweedy	11
Mr. Henry Morris	11
Mr. A. W. Mayo Robson	9
Mr. J. Hardie	6

A letter was read, dated the 6th inst., from Mr. W. G. Dickinson, asking the Council, on behalf of the Committee of the "Society of Members," to appoint a committee to confer with a deputation on the subject of the proposed alterations in the Charter. The Council appointed for this purpose the committee which already exists for the purpose of receiving deputations from Fellows. A petition was read from the London School of Medicine for Women, asking the Council to admit women to the examinations for the diploma of Membership. The matter was referred to the Committee of Management.

Mr. Christopher Heath was re-elected President, and Mr. Reginald Harrison and Mr. Pickering Pick were appointed Vice-Presidents, as we announced last week.

Mr. J. H. Targett was reappointed Pathological Curator.

The next ordinary meeting of the Council is to be held on Monday, the 29th inst.

THE HOME OFFICE INQUIRY INTO THE CASE OF THOMAS WEIR.

WE have received the report of the inquiry ordered by Mr. Asquith, as Secretary of State for the Home Department, into the cause of death of a patient named Thomas Weir of St. Anne's Heath, Virginia Water. The inquiry was held by Mr. Gully, Q.C., the present speaker of the House of Commons, assisted by Dr. Savage, and the specific direction it was to take is given in the following words:—"To report to the Home Secretary upon the treatment of Thomas Weir, upon the sufficiency of the supervision under which it was carried out, and on the regulations, rules, and by-laws in force in the said hospital so far as relates to their adequacy to secure the proper treatment and supervision of insane patients." The inquiry showed that Weir had been subjected to the form of restraint known as "the dry-pack" (an apparatus consisting of a blanket, straps, and webbing, so arranged as to limit the movement of the limbs in cases of maniacal excitement with violence), and that he died of exhaustion and collapse after undergoing the treatment. Dr. Savage, while finding the dry-pack a useful remedy in cases of mania both as a curative and restraining process, is of opinion that in Weir's case the use of the apparatus was excessive. The report goes on to say that in the administration of the treatment "almost every ordinary and proper precaution seems to have been neglected," and gives in detail the reasons for arriving at this severe conclusion. Certain recommendations made by the Lunacy Commissioners last autumn with reference to this case are published as an appendix to the report and receive the concurrence of Mr. Gully and Dr. Savage. The three more important ones run as follows:—(1) That the use of the "dry-pack" in the form employed at the Holloway Sanatorium ought not to be permitted, the older form of packing in blankets without straps being much preferable; (2) that mechanical restraint in institutions for the care of the insane should only be employed upon the direct authority of the superintendent or his official deputy; and (3) that restrained patients should be continuously watched by skilled attendants and visited at short intervals by members of the medical staff.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Helens Urban Sanitary District.—We cannot notice the report as to this district without a brief reference to the former medical officer of health, the late Mr. Robert McNicoll, to whose memory the present medical officer of health, Dr. John Robertson, contributes a fitting obituary notice. Mr. McNicoll practised medicine in St. Helens for fifty years, and for over twenty of those years he acted as medical officer of health to the borough; he was one of the first medical officers of health appointed in England. Those of our readers who can recall Mr. McNicoll's valuable annual reports will not need to be reminded of the excellent and conscientious work which he performed, and as Dr. Robertson aptly puts it, had Mr. McNicoll lived but a few days longer he would have seen the completion of a public testimonial to him in the founding of "The McNicoll Scholarship" at the Cowley Middle Schools. This is a fitting testimony to his memory. There was, Dr. Robertson observes, a decrease in the birth-rate of St. Helens in the middle of 1894, and he attributes it in all probability to the

Digitized by Google

coal strike in the autumn of 1893. Commercial disaster such as this generally, as he points out, influences both the marriage and birth rates. Out of every 1000 births in St. Helens during 1894 31·5 were illegitimate, a proportion higher than in any other of the previous twelve years. In deploring the high infantile mortality Dr. Robertson expresses his satisfaction that the sanitary authority have appointed a female sanitary inspector, and one of her duties is to advise as to the feeding and rearing of young infants. Female factory labour does not, according to the report before us, operate as a cause of infantile mortality in St. Helens, and there is, therefore, Dr. Robertson remarks, no need for artificial feeding. Infantile vaccination appears to be well carried out in St. Helens, and this is in large part due, we are told, to the excellent influence which Mr. McNicoll, as public vaccinator, had in the district.

Blackpool Urban Sanitary District.—Calculated on the average number of persons per house in the case of the six wards of which Blackpool is made up, the population is estimated at 30,337, while on the assumption that the last intercensal increase has been maintained the population is estimated at 28,203. The corrected death-rate for 1894 was 13·45 per 1000. Dr. Jasper Anderson has constructed an interesting table showing the length of residence in Blackpool of each person dying during 1894, and from this it appears that out of 481 deaths only 170 were of persons who were born in the district. Dr. Anderson has also continued his investigations into the causes of the high infantile mortality-rate in Blackpool, and he furnishes a table showing the cause of death and the ages at death of children dying in the district during the ten years 1884–93. The figures obtained he compares with those of 1889–91 for Preston, Leicester, and Blackburn, the three towns having the highest infantile mortality, and also with those for the counties of Hertfordshire, Wiltshire, and Dorsetshire, where the infantile mortality is lowest. The comparison shows that in Blackpool a larger proportion of children are born who only survive their birth for a few days than in any other of the districts with which comparison is made. Taking the deaths in the first month of life it appears that 5078 deaths would occur in Blackpool out of 100,000 births, as compared with 3488 in the three counties and 4947 in the three towns. We wish we had space to reproduce Dr. Anderson's tables, as they are very instructive. Coming to the causes of death, Dr. Anderson finds that prematurity and atelectasis accounted for 3289 deaths out of 100,000 births in Blackpool, as against 1436 and 2428 for the counties and towns respectively, and he thinks that possibly this excess in Blackpool may be due to the fact that the stamina of the inhabitants of Blackpool is not up to the average of that in the three towns, owing perhaps to the immigration of partially worn-out townsfolk into the borough, and he is, too, inclined to think that the social conditions of Blackpool favour premature confinements. In this connexion he refers to the fact of the Registrar-General having drawn attention to the gradual increase in deaths from prematurity and congenital defects in England and Wales during recent years. Particulars are also given by Dr. Anderson of the feeding of 225 children who died between the first and twelfth months of life, and the results show that 51 per cent. were never fed at the breast, whilst of the total number only 25·5 per cent. were fed at the breast during their whole lives.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6395 births and 4033 deaths were registered during the week ending July 13th. The annual rate of mortality in these towns, which had risen in the four preceding weeks from 15·4 to 17·5 per 1000, further increased last week to 19·9. In London the rate was 21·0 per 1000, while it averaged 19·0 in the thirty-two provincial towns. The lowest rates in these towns were 8·9 in Huddersfield, 10·2 in Swansea, 10·5 in Brighton, 11·7 in Halifax, and 12·4 in Cardiff; the highest rates were 22·1 in Leicester, 26·0 in Salford, 26·4 in Preston, 27·4 in Wolverhampton, and 30·2 in Liverpool. The 4033 deaths included 877 which were referred to the principal zymotic diseases, against 494 and 665 in the two preceding weeks; of these, 564 resulted from diarrhœa, 126 from measles, 72 from diphtheria, 54 from whooping-cough, 37 from scarlet fever, 23 from "fever" (principally enteric), and 1 from small-pox. No fatal case of any of these diseases occurred last week in Halifax; in the other towns they caused the lowest death-rates in Brighton, Swansea, Derby, and Huddersfield, and the highest rates in Salford, West Ham, Leicester and Preston. The greatest mortality from measles occurred in Manchester, and West Ham; from whooping-cough in Birkenhead, Oldham, and Burnley; from "fever" in Sunderland; and from diarrhœa in Wolverhampton, Bradford, Salford, Leeds, Preston, and Leicester. The mortality from scarlet fever showed no marked excess in any of the large towns. The 72 deaths from diphtheria included 50 in London, 5 in West Ham, and 4 in Liverpool. One fatal case of small-pox was registered in London, but not one in any of the thirty-two large provincial towns. There were 72 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, July 13th, against 22, 34, and 42 at the end of the three preceding weeks; 36 new cases were admitted during the week, against 8, 25, and 17 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2241, against 1732, 1894, and 2044 on the three preceding Saturdays; 342 new cases were admitted during the week, against 251, 319, and 311 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 160 in each of the two preceding weeks, rose last week to 187, but were 5 below the corrected average. The causes of 53, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Nottingham, Oldham, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Salford, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·2 and 19·4 per 1000 in the two preceding weeks, further rose to 20·3 during the week ending July 13th, and was 0·4 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·3 in Dundee and 16·5 in Edinburgh to 26·8 in Greenock and 32·0 in Paisley. The 585 deaths in these towns included 72 which were referred to diarrhœa, 18 to whooping-cough, 14 to measles, 10 to "fever," 6 to scarlet fever, 1 to diphtheria, and not one to small-pox. In all, 121 deaths resulted from these principal zymotic diseases, against 78 and 98 in the two preceding weeks. These 121 deaths were equal to an annual rate of 4·2 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 28, 48, and 57 in the three preceding weeks, further rose to 72 last week, of which 40 occurred in Glasgow, 11 in Paisley, and 7 in Greenock. The deaths referred to whooping-cough showed a further increase upon the number recorded in recent weeks, and included 10 in Glasgow and 3 in Dundee. The fatal cases of measles, which had been 14 and 18 in the two preceding weeks, declined again to 14 last week, of which 5 occurred in Glasgow, and 2 each in Edinburgh, Leith, Paisley, and Greenock. The deaths from scarlet fever, which had been 1 and 5 in the two preceding weeks, further rose to 6 last week, and included 3 in Edinburgh and 2 in Glasgow. The 10 fatal cases of "fever" considerably exceeded the number in any recent week, and included 4 in Glasgow, 2 in Edinburgh, and 2 in Leith. The deaths referred to diseases of the respiratory organs in these towns, which had been 99 and 79 in the two preceding weeks, declined again to 60 last week, but exceeded by 19 the number in the corresponding week of last year. The causes of 46, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 20·1 to 24·9 per 1000 in the three preceding weeks, declined again to 20·0 during the week ending July 13th. During the thirteen weeks of last quarter the death-rate in the city averaged 27·3 per 1000, the rate during the same period being 16·7 in London and 18·8 in Edinburgh. The

Digitized by Google

134 deaths registered in Dublin during the week under notice showed a decline of 33 from the number in the preceding week, and included 16 which were referred to the principal zymotic diseases, against 9 and 11 in the two preceding weeks; of these, 10 resulted from diarrhœa, 3 from "fever," 2 from small-pox, 1 from diphtheria, and not one either from measles, scarlet fever, or whooping-cough. These 16 deaths were equal to an annual rate of 2·4 per 1000, the zymotic death-rate during the same period being 5·3 in London and 2·3 in Edinburgh. The fatal cases of diarrhœa, which had increased from 3 to 6 in the three preceding weeks, further rose to 10 last week. The 3 deaths referred to different forms of "fever" exceeded the number recorded in any recent week, and the 2 fatal cases of small-pox were the first registered within the city during the past three weeks. The 134 deaths in Dublin last week included 26 of infants under one year of age, and 27 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the numbers recorded in the preceding week. Seven inquest cases and 5 deaths from violence were registered; and 41, or nearly a third, of the deaths occurred in public institutions. The causes of 13, or nearly 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

CHITRAL.

THE following paragraphs have been published in the *London Gazette*:—

"War Office, July 16th, 1895.—The Queen has been graciously pleased to signify her intention to confer the decoration of the Victoria Cross upon the following officer, whose claim has been submitted for Her Majesty's approval, for his conspicuous bravery during the sortie from Chitral Fort on March 3rd last, as recorded against his name:—Surgeon-Captain Harry Frederick Whitchurch, Indian Medical Service. During the sortie from Chitral Fort of 3rd March last, at the commencement of the siege, Surgeon-Captain Whitchurch went to the assistance of Captain Baird, 24th Bengal Infantry, who was mortally wounded, and brought him back to the fort under a heavy fire from the enemy. Captain Baird was on the right of the fighting line, and had only a small party of Gurkhas and men of the 4th Kashmir Rifles. He was wounded on the heights at a distance of a mile and a half from the fort. When Surgeon-Captain Whitchurch proceeded to his rescue the enemy, in great strength, had broken through the fighting line; darkness had set in, and Captain Baird, Surgeon-Captain Whitchurch, and the Sepoys were completely isolated from assistance. Captain Baird was placed in a dooley by Surgeon-Captain Whitchurch, and the party then attempted to return to the fort. The Gurkhas bravely clung to the dooley until three were killed and a fourth was severely wounded. Surgeon-Captain Whitchurch then put Captain Baird upon his back and carried him some distance with heroic courage and resolution. The little party kept diminishing in numbers, being fired at the whole way. On one or two occasions Surgeon-Captain Whitchurch was obliged to charge walls, from behind which the enemy kept up an incessant fire. At one place particularly the whole party was in imminent danger of being cut up, having been surrounded by the enemy. Surgeon-Captain Whitchurch gallantly rushed the position, and eventually succeeded in getting Captain Baird and the Sepoys into the fort. Nearly all the party were wounded, Captain Baird receiving two additional wounds before reaching the fort."

"India Office, July 15th.—The Queen has been graciously pleased to nominate and appoint Surgeon-Major George Scott Robertson, C.S.I., Indian Medical Service, British Agent, Gilgit, to be a Knight Commander of the Most Exalted Order of the Star of India."

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments and transfers are ordered:—Surgeon-Captain T. W. Gibbard to hold collateral charge of the Civil Surgeoncy at Shwebo, vice Surgeon-Captain K. Prasad; Surgeon-Captain K. Prasad to be Civil Surgeon of the Toungoo District, vice Surgeon-Captain A. R. P. Russell; Surgeon-Captain A. R. P. Russell to be Superintendent of the Rangoon Central Gaol, vice Surgeon-Major R. E. S. Davis; and Surgeon-Major R. E. S. Davis to be Junior Civil Surgeon and Superintendent of the Lunatic Asylum, Rangoon, vice Surgeon-Lieutenant-Colonel O. Baker, who departs on leave. Surgeon-Major S. J. Thomson (Bengal), Deputy Sanitary Commissioner, North-West Provinces and Oudh, to be Sanitary Commissioner, North-West Provinces and Oudh, *sub pro tem*, from date on which he assumed charge of the office from Brigade-Surgeon-Lieutenant-Colonel G. Hutcheson, M.D. Surgeon-Lieutenant-Colonel A. S. Jayakar (Bombay), Agency Surgeon at Maskat, is appointed to hold Charge of the current duties of the Office of Political Agent at Maskat, in addition to his other duties, until further orders. Surgeon-Captain H. E. Drake-Brockman, Civil Surgeon, 2nd class, whose services have been replaced at the disposal of the Government of the North-West Provinces by the Government of India, Home department, to the Muttra District. Surgeon-Major E. S. Brander, Civil Surgeon, from Muttra to Sitapur. Surgeon-Major C. C. Vaid, Civil Surgeon, from Sitapur to Hardoi. Surgeon-Captain D. W. Scotland, Officiating Civil Surgeon, from Orai to Azamgarh.

NAVAL MEDICAL SERVICE.

The following appointment has been made:—Surgeon and Agent: William Doughty at Torcross and Hallsands.

VOLUNTEER CORPS.

Artillery: 1st Kent (Eastern Division, Royal Artillery): Surgeon-Major. C. Arrol, M.D., to be Surgeon-Lieutenant-Colonel. 1st Lincolnshire (Western Division, Royal Artillery): The undermentioned gentlemen to be Surgeon-Lieutenants:—Thomas William James Allen; George Henry Grimoldby. 2nd West Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Lieutenant J. C. Wright is appointed Lieutenant. *Rifle:* 2nd Volunteer Battalion the Royal Welsh Fusiliers: Surgeon-Lieutenant W. D. Fraser, M.B., to be Surgeon-Captain.

INDIA: MEDICO-MILITARY NEWS.

THE latest Anglo-Indian papers contain several interesting items of intelligence, some of which may be briefly summarised for the information of our readers. The question of the future policy as to the retention or not of Chitral is engaging very serious attention, and a great difference of opinion prevails on the subject. The advocates and followers of a "forward policy" are, of course, for its retention, but the opponents of this policy are, it seems to us, able to urge many very weighty objections, especially from a statesmanlike and finance point of view. The matter is one for grave consideration, and as the force will, it is understood, remain until September before returning to India the present Government will have ample time for deliberation. Meanwhile we learn that there is a good deal of sickness amongst the European troops at Chitral and heavy casualties among the baggage animals, and the daily cost incurred by the forces remaining over the frontier is very heavy irrespective of what will be the amount of the initial and final expenditure. Enteric fever is said to be somewhat prevalent in the Chitral relief force and the British troops suffer a good deal from exposure. The field hospital at Chitral is hard worked. According to telegrams from Simla there were on June 19th last 18,964 troops engaged on the relief expeditionary force. Of these 6611 were British, of whom 286 were on the sick list, while out of 12,348 native troops only 228 were returned as ineffective from sickness. The chief sickness was amongst the Gordon Highlanders, King's Own Scottish Borderers, the Buffs, Bedfordshire Regiment, and King's Royal Rifles. The native force is comparatively healthy. The season in India has apparently been a very hot one, but the occurrence of the rains has diminished the temperature and lessened the sickness. Heat apoplexy has been prevalent among the troops at Peshawar and Kurrachee, and several deaths from this cause have occurred.

THE QUEEN AT ALDERSHOT.

Accompanied by Princess Beatrice, the Marchioness of Lorne, and Prince and Princess Henry of Battenberg, Her Majesty arrived at Aldershot on Friday, July 12th, for a two days' visit, and evinced great interest in a physical display by a class of non-commissioned officers who have just completed a six months' course of training. As we pointed out in our article on the Royal Military Tournament[1] these men are trained under the direction of Colonel Fox,

[1] THE LANCET, June 1st, 1895.

Digitized by Google

by a system which develops every muscle of the body, while the mental powers, so far as they affect alertness and presence of mind, are trained to a degree that could not be attained under the old system. Other physical displays also took place, including one by the Egyptian fellaheen under Sergeant-Major De Vere. The Royal visit was brought to a close by a review of the troops on Laffan's Plain on the following Saturday.

A PORTABLE COOKING APPARATUS.

According to the *Army and Navy Gazette*, Staff-sergeant Fowler of the Medical Staff Corps has invented a portable cooking apparatus which presents some new features. The object is to furnish the army medical service with the means of providing patients under all circumstances with the same varieties of diet that are obtainable in station hospitals. It is claimed that the apparatus will cook with half the camp allowance of fuel and is capable of supplying large quantities of boiled or distilled water.

HOSPITAL FOR INFECTIOUS DISEASES AT PESHAWAR.

The Government of India have sanctioned the estimates for the erection of a special hospital for contagious diseases for all native troops at Peshawar.

Surgeon-Lieutenant-Colonel Coates, A.M.S., Surgeon-Captain Russell, A.M.S., and Surgeon-Captain Key, Volunteer Medical Staff, have been selected as medical officers at the Camp of Instruction of the National Artillery Association at Shoeburyness on Aug. 3rd.

The examination at the end of the seventieth or summer session of the Army Medical School will commence on July 23rd and terminate on July 29th. The session will be brought to a close on July 31st, when the prizes will be presented to the successful candidates by Surgeon-General Sir Joseph Fayrer, K.C.S.I.

It is stated that the Government of India has sanctioned an estimate of Rs. 11,964 for building a special hospital for contagious diseases for all native troops at Peshawar.

Correspondence.

"Audi alteram partem."

"THE PHYSICS OF CARDIAC SOUNDS AND MURMURS."

To the Editors of THE LANCET.

SIRS,—Under the above heading there is in THE LANCET of June 15th and 22nd a long article by Dr. J. T. R. Davison which ought not to be allowed to pass without comment. We may agree with Dr. Davison that the closure of the aortic valves is due to the increase of tension in the aorta caused by the incoming current of blood. By the laws of fluid pressure, and in consequence of the existence of the pouches of Valsalva, the sigmoid valves will close as soon as the pressure on their aortic aspect exceeds that on their ventricular aspect. But his theory that the second sound "is directly produced by the latter part of the ventricular contraction, owing to the semilunar valves being thrown into sonorous vibrations by the latter part of the ventricular stream impinging against the ventricular surface of these valves in the act of their closing in," is at once condemned by the observations of Roy and Adami with the myocardiograph.[1] For the tracings obtained by means of this instrument from the hearts of mammals by these skilled and careful experimenters prove conclusively that the second sound does not occur until the ventricular contraction has ceased, at the end of an interval, measuring two-thirteenths of the whole cardiac cycle, subsequent to the closure of the sigmoid valves and synchronously with the sudden diastolic expansion of the ventricle. Again, we may agree with Dr. Davison that the mitral valve closes as soon as the ventricular tension has been raised so as to exceed the auricular. But his theory that "the first sound is the direct result of the auricular contraction," being caused by the impact of the stream from the auricle on the closed mitral valve, is easily disproved by the myocardiograph. For the commencement of the first sound is precisely synchronous with the sudden systolic rise of the ventricular tracing, and it continues during nearly the whole period of the ventricular contraction. And this extraordinary theory involves the astounding proposition that while the mere tail-end of the contraction of the thin-walled auricle is capable of producing the loud first sound, the contraction of the thick-walled ventricle, which must cause great strain of the mitral segments (as is proved by the very existence of the chordæ tendineæ), is incapable of producing any sound at all. Dr. Davison even maintains that the cardiac impulse is due to the auricular and not to the ventricular contraction, and he offers as proof the observation that it occasionally distinctly precedes the carotid pulsation. As if the blood-current took no time at all to pass from the ventricle to the carotid, and as if the time required might not be, by various circumstances, occasionally prolonged.

Dr. Davison attempts to explain cardiac murmurs by observations of the sounds heard on auscultating "a small piece of fresh intestine" filled with water and ligatured at both extremities, when an oblique stream of water is suddenly introduced into it through a tube fastened into one of its ends, quite regardless of the dissimilarity between the continuous wall of such an intestine and the damaged valves of heart disease, and of the obvious fact that "a small piece" of intestine full of stagnant fluid and with its ends ligatured can in no way represent the physical conditions either of the empty ventricle at the instant of diastolic expansion or of the aorta through which the blood stream is flowing.

I am, Sirs, yours truly,

DAVID B. LEES, M.D., F.R.C.P.

Weymouth-street, W., July 14th, 1895.

IRISH WORKHOUSE REFORM.

To the Editors of THE LANCET.

SIRS,—In a communication addressed to you on May 31st by Sir Philip Smyly and Mr. Hepburn on behalf of The Irish Medical Association it was stated that "on carefully examining in detail the replies from seventy-nine (medical) officers of workhouses who had furnished information), we find that forty-three infirmaries have no trained nursing, the nursing being entirely in the hands of pauper women." It has since been pointed out to this council that the latter part of this sentence is inaccurate. We are informed, and believe, that in forty-three out of the seventy-nine infirmaries no trained nurse is employed, but that, in many instances, the nursing is under the supervision of untrained nurses, many of whom are as competent as an untrained nurse can be expected to be. As regards these infirmaries it is not correct to say that "the nursing is entirely in the hands of pauper women," and the council therefore begs to withdraw that statement and to express its regret that a statement capable of such an interpretation should have been made. The presence of a single untrained nurse in a workhouse infirmary containing (on average) sixty-three patients cannot however materially modify the assertion that the nursing arrangements of such a hospital are totally insufficient, especially when the multifarious duties devolving upon this untrained nurse are considered. She is practically the porter of the infirmary, must keep all doors leading to the house and to the female wards locked, and must open them herself when egress or ingress are needed; must serve out all food and keep an account of it, be responsible for all clothes received from the laundry and sent to it, and generally oversee all the pauper women employed. Manifestly an official charged with those duties is more of a matron than a nurse, and can contribute very little to the care and comfort of the sick inmates.

The council has learned with much satisfaction that the Local Government Board has addressed to the guardians of each union a circular note requesting them to obtain from the medical officer a specific report as to the nursing, sanitation, and diet in the workhouse hospital, and suggesting that the visiting committee of the guardians might with advantage confer with the medical officer respecting any changes which would conduce to the comfort of the sick inmates. The council, while highly approving of the course suggested, submits that the reports and conferences indicated would prove much more effective if the visiting committees and the medical officers were supplied with some brief suggestions as to the requirements of a well-ordered workhouse

Digitized by Google

infirmary, and with a series of definite questions as to whether such requirements are or are not fulfilled. It is scarcely to be expected that all visiting committees and their officers are *au courant* with the conditions as to air, space, ventilation, sanitary accommodation, &c., which are regarded by modern sanitarians as an indispensable minimum for a workhouse infirmary, and the council, therefore, apprehends that unless some guidance in this direction is afforded to the administrators of workhouses, the efforts of the Local Government Board to arrive at the truth may prove to some extent abortive. It is, unfortunately, quite unnecessary to exaggerate the deficiencies of the workhouse infirmary system, and the association has no other object than to elicit the truth, the whole truth, and nothing but the truth, respecting the accommodation for the sick poor throughout the country.—We are, Sirs, yours truly,

AUSTIN MELDON, J.P., D.L.,
Past President R.C.S.
Dublin, July 15th, 1895. ARTHUR H. BENSON, F.R.C.S.I.

"IS METEOROLOGY A SCIENCE?"

To the Editors of THE LANCET.

SIRS, — Dr. Gowers invites me to define the word "science." I should be sorry to attempt to do what he finds so difficult, but I agree with him that the term turns much upon the use of words. I also agree that the expression may be applied in a very general sense to all regions of knowledge where observations are made and inferences drawn. I have already said that in this large sense as a branch of knowledge meteorology may be classed amongst the sciences. At the same time, it seems to me to stand quite alone and is not amenable to the usual methods of scientific inquiry. Observation does not make a science. The ancients were good observers, but it was left to the moderns to adopt altogether new methods of investigation and experimentation. At the present time if we wish to discover the nature of any object we do so in connexion with its surroundings. If these are changed the qualities of the object itself change, so that under different conditions the same thing may be solid or liquid; it may freeze or scorch the hand which touches it. Its qualities could not spontaneously change in this manner; they must be due to an external force. Man can have no existence outside the atmosphere any more than a fish out of water. In astronomy all the laws have reference to the relation of the heavenly bodies to one another. Newton first showed us how all their movements are dependent on the forces of attraction between them. The slanting axis of the earth, causing the rays of the sun to fall upon the earth with different obliquities, determines the characters of the animal and vegetable world. Even in astronomy we have a counterpart of the experimental method, for should the sun be eclipsed men of the greatest eminence will traverse the globe to study its light under the new conditions, or to observe a transit of Venus to enable them to calculate the sun's distance. Moreover, should any irregularity appear in the celestial world we seek for a cause, for it was considered impossible for Uranus to display perturbations in its orbit without the existence of a Neptune. I cannot, therefore, agree that meteorology is as much a science as astronomy. It seems to me that in all branches of inquiry which are called scientific we are investigating the relation of different bodies to one another. We alter the surroundings, and the phenomena or character of the object also alter. If we discover that a change has taken place in an object in nature we ask what is the external force which has been acting upon it. Now, as regards the earth and its satellite we know enough to understand why the seasons and the tides occur, but we know nothing of the altered conditions which produce the daily changes styled "weather." We know nothing of the earth's environments except the sun. All we do at present is to make use of the telegraph to inform us as to what is going on at a distance, but we predict nothing. No one foresees whether we shall have a cold or hot winter and a dry or wet summer. It seems to me that we have no data whatever to guide us. In all other branches of science we study the effects of the surroundings on objects, or the relation of things to one another, since every object is conditioned or depends in an unknown measure on its environments. In meteorology no method of this kind is or can be pursued, for we know nothing of the earth's environments but the sun and moon, and the latter has long been put out of court. It was this view of the matter that made me say it was a fair question to ask, Is meteorology a science? Dr. Gowers asks, What is the difference between science and knowledge? I should answer, They run into each other. Science is systematised knowledge—as, for example, in the case of the rotundity of the earth. At the time when people believed the earth was flat the arguments for its being round might be called scientific, but now that the shape of the earth is accepted by everyone it becomes common knowledge and ceases to be science. I must trespass no more on your space with a subject foreign to the designs of THE LANCET.

I am, Sirs, your obedient servant,
Grosvenor-street, W., July 15th, 1895. SAMUEL WILKS.

To the Editors of THE LANCET.

SIRS,—In reference to the leading article in THE LANCET of June 29th last, on the scientific position of meteorology, I beg to offer a few comments on the position taken up by the writer in the *Edinburgh Review*. He suggests that "it is not a science" if it consists merely in observing and recording temperatures and pressures, but he may be referred in confutation of this opinion to a paragraph further on on astronomy. He there says "that thousands of years had passed in patient observation before the motion of the heavenly bodies was understood." Astronomy has usually been considered a sublime and respected science for ages past; yet it chiefly consists in observing the heavens daily and hourly by instruments and recording the matters seen. Meteorology really should be considered a kindred and allied science to astronomy, of equal calibre and scientific position, as both are founded on the observations of natural phenomena and require the use of instruments of precision. Further on, forecasting of weather is considered derogatory to the scientific position of meteorology, but the laws of probabilities are included in the science of mathematics, and prognosis is part of the science and art of medicine.

A serious view of the character of meteorological science has not yet, however, been entertained by the British public, and the results of its labours and aspirations are still tabooed and neglected officially. We have seen the consequences of this abnegation in the disasters that befall water companies in winter by frozen pipes, and in summer by dried-up reservoirs, by ignoring past meteorological investigations and results. We have seen it neglected in warlike operations, when John Bull could not believe that the Crimea would be visited by such an Arctic winter (in 1854-55), as he estimated that it would only be like such as he was accustomed to see in Hyde Park. The authorities fifty years further back (in August, 1809) had not the means of knowing what the climate of Walcheren was like, or that it was any different from that of the Thames; and so they saw thousands of our soldiers die and perish under a broiling sun and the paludal mists of the Polders. It is scarcely credible that the War Office of the time had not provided our medical officers with meteorological instruments for use in the expedition in 1801-2, and so they came and went knowing nothing of the climate they lived in. Both the French and Indian armies had seen to this provision having been made in 1801-2 for ascertaining the features of the weather and atmosphere of Egypt during their marches through the country and in stationary camp quarters. If meteorology, then, is to be of any good it must be acknowledged as a science fit to minister to the wants and life of the nation, by its professors and workers being recognised as investigators and accumulators of valuable information. I am, Sirs, yours faithfully,

July 16th, 1895. OBSERVER.

P.S.—In a lecture by Mr. Clement Wragge before the Royal Society of Tasmania, reported by the *Hobart Mercury*, May 22nd, 1895, the following words occur:—"Mr. Wragge, who was received with applause, referred to the distinction between the sciences of astronomy and meteorology. The study of the latter enabled forecasts to be made which were of infinite value to all kinds and conditions of men."

THE SOCIETY OF MEDICAL PHONOGRAPHERS.

To the Editors of THE LANCET.

SIRS,—Will you kindly grant me space to express a hope that any members of the profession who use shorthand, and may be intending to join our society, will do so at once by

Digitized by Google

communicating with Dr. Neil, Wasneford Asylum, Oxford? We are anxious to include as many as possible before the general meeting on the 30th. Although we have now 154 members we find that there are still many who should join and have not yet done so. Among the visitors whose presence we hope for on the 30th (at 4 P.M. at 20, Hanover-square) are General Sir Charles Wilson, K.C.B., K.C.M.G., the Director-General of Military Education, and Dr. J. H. Gladstone, F.R.S., who has used phonography in scientific work since 1846. I may add that the varied service the society is rendering to its members far exceeds, both in degree and character, our early anticipations. To this many members could bear strong testimony.

I am, Sirs, yours faithfully,
W. R. GOWERS, President.

Queen Anne-street, Cavendish-square, W., July 13th, 1895.

"THE REMUNERATION OF MEDICAL OFFICERS TO PROVIDENT ASSOCIATIONS, CLUBS, ETC."

To the Editors of THE LANCET.

SIRS,—If Dr. Paget Thurstan accepts my figures, I must ask him to do so having some regard to the statements which accompany them. My illustration represented an outside estimate, for the reasons which I gave, but Dr. Thurstan has fallen into two further errors—first, in assuming that each person was necessarily attended professionally on each of his nine days' sickness; and, secondly, in concluding that all of the attendances were visits. At least two-thirds of the patients call on the medical officer. I am far from upholding that the present rates are adequate; in fact, I distinctly said the opposite—viz., that we must look forward to raising them. But I say that when a medical man receives regularly £200 a year for attending daily either at their homes or at his surgery some fifteen persons (1½ per cent. of 1000) he is in most instances glad to get it.

I am, Sirs, yours faithfully,
July 16th, 1895. W. G. DICKINSON.

*** This correspondence must now cease.—ED. L.

"THE DANGERS OF COCAINE."

To the Editors of THE LANCET.

SIRS,—Your annotation on "The Dangers of Cocaine" in THE LANCET of July 6th will, I hope, attract attention to the increasing use of cocaine. You speak, however, of persons getting "into the habit" of taking it. But in the inquest to which as I suppose you refer there was no evidence whatever that the deceased had used it in this way. On the contrary, the evidence was conclusive that this bottle of medicine had been in the possession of the deceased for at least twelve months. The points that need to be elucidated are whether, say, ten grains of the mixture, as prescribed for application to the gums, could kill in a short time if taken by mistake, or whether the explanation is not rather to be found in the possibility of a fungus growing in the bottle if kept for a length of time. In either case it is surely time that cocaine should be scheduled as a poison or that at any rate some special label should be placed on the bottle as a caution.

I am, Sirs, yours faithfully,
July 13th, 1895. ONE WHO WISHES TO KNOW.

ERRATUM.—Dr. Alderson's letter in the last issue of THE LANCET should obviously have been headed Fracture of the Lower End of Humerus, not "Femur."—ED. L.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Small-pox: Vaccination and Revaccination.

DR. HOPE, the medical officer of health, in his last annual report dealt very exhaustively with small-pox as it appeared last year, and showed very conclusively that but for the activity with which every case was traced and followed up there would most certainly have been a very serious epidemic of the disease. Liverpool has always a very large proportion of what may be called "migratory citizens," and it must be obvious that these have in times of epidemic the capacity of carrying the infection to all parts of the city, and even beyond this limit. The lamentable case which occurred on board the *Clarence* training ship will be remembered as a notable instance. It is to be hoped that the scare produced will induce all those citizens who have not been revaccinated to adopt this most satisfactory mode of protection. It may also be remembered that the local watch committee passed a resolution to the effect that all candidates for the police force should undergo revaccination to the satisfaction of the police surgeon. How necessary this is may be judged from the fact that out of thirteen candidates who presented themselves to the surgeon on a recent occasion only two had been revaccinated, one of these cases being very doubtful. Of the remaining eleven, one refused to undergo vaccination, and the remainder submitted. Another candidate, who appeared more recently, had been vaccinated in infancy and had contracted small-pox mildly during the recent epidemic in Warrington. He was, therefore, excused from revaccination.

An alleged Female Thief aged ten simulating Fits.

A local detective was induced to watch the movements of a girl aged ten, which were somewhat suspicious. He saw her with her hand in the pocket of a passer-by, and on seizing it the girl apparently went into a fit. On taking her to the hospital the resident surgeon pronounced it to be a case of shamming. The girl was accordingly taken to Bridewell, and on the house of her parents being searched several articles of stolen property were found secreted there. The parents professed to be wholly ignorant of the girl's alleged thefts. The case is still *sub judice*.

Assaults on the Police.

In consequence of the action of the stipendiary magistrate in sending to prison those charged with assaults on the police (unless it were a first offence), a period of two months recently passed without any member of the force being incapacitated from duty. Unfortunately, the spell has been broken and assaults have again become serious. In one case an officer was struck on the head with the buckle of a belt, producing a scalp wound, with very severe hæmorrhage; in another the officer was bitten, a dangerous and disgusting form of assault which has too often followed a drinking bout. In each case the offender was sent to gaol with hard labour.

July 16th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Dr. David J. Brakenridge, Edinburgh.

AFTER an illness of about two months' duration Dr. David J. Brakenridge died at his residence in Edinburgh on July 10th, at the age of fifty-six years. Dr. Brakenridge was a graduate of the University of Edinburgh and a Fellow of the Royal College of Physicians of Edinburgh. Although comparatively young he had completed his years of service as a physician to the Royal Infirmary, and on his retirement a few years ago was made a consulting physician to the institution. He was also a physician to Chalmers Hospital at the time of his death. Dr. Brakenridge took a somewhat active part in medical affairs, especially at the Royal College of Physicians, and being a man of decided individuality made himself a good deal felt. He was always honest and honourable, however wrong his policy and attitude might be considered by those disagreeing with him. As a clinical teacher he gave great promise in the earlier years of his connexion with the Royal Infirmary, and he always attracted a select body of students. His mind was, perhaps, too subtle and critical to attract the ordinary student, who was seeking hard and fast rules and indications to enable him to pass examinations. The best known of his contributions to medical literature are those which dealt with the administration of disinfectants for the prevention and treatment of scarlet fever and other infectious diseases, caffein as an adjunct to digitalis in cardiac cases, and more recently his introduction and advocacy of blood transfusion in the treatment of pernicious anæmia. He took a great interest in the epidemic of influenza which appeared in Edinburgh in 1890, and opened a discussion on the subject at the Medico-Chirurgical Society. Had he lived he would in ordinary

Digitized by Google

course have been offered the presidential chair at the College of Physicians. He was much esteemed by those who knew him intimately, and his loss is very deeply mourned by a large circle of friends. He was buried on Saturday, his funeral being attended by almost every member of the profession in Edinburgh. His wife survives him, but there are no children.

Public Health Matters in Edinburgh.

At the meeting of the town council of Edinburgh last week it was remitted to the Public Health Committee "to consider the suitability of the ground adjoining Craiglockhart poorhouse belonging to the city parish council as a site for the new city hospital, with powers to employ experts, if so advised, to negotiate with the parish council to complete a provisional agreement for the acquisition of a portion of the property at a price to be fixed by arbitrators mutually chosen." It was also stated that there were 193 patients in the city hospital, of whom 134 were suffering from scarlet fever. There had been no cases of small-pox for six weeks, and negotiations were being carried on with the Trinity Hospital Committee for a piece of ground to which it was hoped the small-pox hospital in the Queen's Park would be soon removed.

Medical Examinations in Edinburgh.

The July examinations in Edinburgh for the Scottish Triple Qualification are almost concluded; and this week the second professional examination will begin at the University, while at the end of the week the first professional will begin.

Edinburgh Royal Society.

At the Edinburgh Royal Society this week Professor T. R. Fraser made another communication on snake poison and immunity produced by the action of anti-venene. In serum therapeutics immunity was obtained by subcutaneous injection, but the method was attended with inconvenience which might be avoided by introducing the poison through the stomach. Serpent's venom was destroyed or nearly so in the stomach, so that when introduced in that way it was inert. He had, however, made experiments which showed that a measure of resistance could be induced by administration in this way. Some of his results he thought might explain the immunity enjoyed by certain snake-charmers in India, for subcutaneous injection was not likely to be the method employed by them for the introduction of the protection-producing venom. The results might also explain the protection possessed by venomous serpents. The anti-venene obtained from serpents themselves was, however, not so effective as that obtained artificially, but he thought the natural anti-venene might be increased, and a sufficiently powerful anti-venene obtained very rapidly by injecting successive doses of venom into the serpents themselves. If this should prove to be the case, a most valuable means of rapidly producing anti-venene would be available, and Professor Fraser will have not only thrown light on a most interesting question, but provided means for saving many lives by counteracting the bite of the more poisonous snakes. Our medical officers in the East will doubtless put this work to the test of practical application as soon as material is available for the purpose; for it is there, and not at home, that the value of Professor Fraser's work will have to be practically tested.

University of Glasgow.

The following appointments to lectureships at Queen Margaret College are intimated:—Mr. James Blyth, F.R.S.E., Natural Philosophy; Mr. Thomas Gray, B.Sc., Chemistry; Dr. C. O. Hawthorne, Materia Medica and Therapeutics; Dr. J. Lindsay Steven, Pathology; Dr. J. Wallace Anderson, Practice of Medicine; Dr. Alexander Tille, German Language and Literature. Dr. W. J. Fleming has resigned his lectureship on Surgery and Clinical Surgery, as his term of office as Surgeon to the Royal Infirmary will expire before the commencement of the next winter session. The University Court will proceed to fill the vacancy at their meeting on the 26th inst. On the same date the Court will also make an appointment to the Chair of Divinity, rendered vacant by the resignation of Professor Dickson. The term of office of Dr. Ralph Stockman as Examiner in Materia Medica and Therapeutics and that of Mr. Aikman, B.Sc., as Examiner in Chemistry having expired, these positions are now declared vacant. Candidates must send in their applications before the 25th inst. Whatever views may be held as to the general policy of the Scottish University Commissioners, one of their latest ordinances will almost certainly receive unanimous approval. This is the ordinance abolishing the stamp duty on the degree of M.D. It has been the law hitherto that on proceeding to that degree the graduate must pay the sum of £10 3*s.* as Government duty. He will now only have to pay the University fee of five guineas. I observe from the University Calendar just issued that the application of the medical lecturers at Queen Margaret College to take part in the degree examinations has been refused. It is difficult to understand the reason for this refusal. The policy of the Scottish University system insists upon the importance of the teacher taking a prominent part in the examination of his own students, but under the present arrangement, whilst this policy is put into practice with regard to the men students, the teachers of the women students are excluded from any part in the examination. This is certainly not equal treatment for the two sexes.

Medical Magistrates.

In the list new of justices of the peace for Ayrshire are the names of Dr. Alexander Macleod M'Rae, Rankinston, and Dr. William Alexander Caskie, Largs.

The Ambulance Challenge Shield.

The Ambulance Challenge Shield, which has been won this year by the 1st Volunteer Battalion Highland Light Infantry, was on the 9th inst. formally presented to Colonel R. C. Mackenzie on behalf of the battalion, and by him handed over to Bailie Primrose for safe custody for the year by the Corporation of Glasgow. The ceremony took place in the City Chambers and was witnessed by a large number of volunteer medical officers as well as by representatives of the general public. The presentation was made by Surgeon-Lieutenant-Colonel William R. Smith, vice-president of the Volunteer Medical Association. He explained that the challenge shield had been instituted for the purpose of stimulating ambulance work in the volunteer regiments throughout the country, and he hoped that the fact that it had come north of the Tweed would have a good influence on ambulance training in the whole of Scotland. He congratulated the successful competitors, and paid a tribute to Surgeon-Lieutenant Swanson, under whom the winning team had been trained. Surgeon-Lieutenant-Colonel Smith also intimated the reception of a letter from the Duke of Cambridge, in which His Royal Highness expressed it as his wish and pleasure that it should be publicly announced that he congratulated the 1st Volunteer Battalion Highland Light Infantry on the distinguished honour which their representatives had obtained. The shield has been placed in the Corporation galleries, and has aroused much interest in the city.

University of Aberdeen.

The following gentlemen have been appointed examiners in the Faculty of Medicine for 1895–96:—Botany: R. J. Harvey Gibson, M.A. Aberd., University College, Liverpool. Zoology: J. A. Thomson, M.A. Edin., School of Medicine, Edinburgh. Chemistry: John Hunter, F.I.C., F.C.S., School of Medicine, Edinburgh. Anatomy: Thos. W. Griffith, M.D. Aberd., Yorkshire College, Leeds. Physiology: W. H. Thompson, F.R.C.S., Queen's College, Belfast. Materia Medica: Francis Warner, M.D. Lond., London. Medical Jurisprudence and Public Health: Fras. J. Allan, M.D. Edin., London. Pathology: Jas. Lorrain Smith, M.A., M.D. Edin., Cambridge. Medicine: J. Rose Bradford, M.D., D.Sc. Lond., F.R.S., London. Surgery: John C. Ogilvie Will, M.D. Aberd., Aberdeen. Midwifery: John W. Ballantyne, M.D. Edin., School of Medicine, Edinburgh.

July 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Poisoning in a Young Ladies' Boarding School.

ANOTHER death has occurred in the Limerick Convent. The victim in this instance was one of the boarders, a young lady aged eighteen, the daughter of Mr. Edward O'Flynn, J.P., a resident of Cork. A sad feature in the case was that the holidays were at hand and the parents were looking forward to the pleasure of seeing their daughter within a few days. Sir Charles Cameron has not yet completed his analysis, and the nature of the poison still remains a mystery.[1] However,

[1] Sir Charles Cameron's description of his investigation will be found on page 147.—ED. L.

Digitized by Google

a statement of the cook may tend to elucidate matters. In her evidence she says she was doubtful with regard to the freshness of one of the eggs used in making the custard, and the custard was made on the day prior to that on which it was eaten. It must be remembered that the weather was very hot, and it is quite possible that this egg caused an extensive development of ptomaines in the whole custard. As I have already mentioned, two nuns were the only inmates of the institution who escaped poisoning, and they had not partaken of the custard. Sir C. Nixon was brought down from Dublin to assist the local medical men in treating the sufferers and investigating all the circumstances of the extraordinary occurrence. Though the lives of all the patients cannot yet be pronounced to be out of danger, the medical men are very hopeful that no more deaths will occur. Meantime the report of the analyst is anxiously looked forward to, not alone by the general public, but also by medical practitioners, who are naturally interested in the scientific aspects of the case.

The Elections: Attack on a Medical Man.

The contest in Cork lies between Parnellites and Anti-Parnellites, and the political leanings of one of the local medical men are well known to incline towards the Anti-Parnellites. Last Sunday whilst driving in the suburbs he was met by a crowd returning from a Parnellite meeting and was struck on the head by either a hand or stick. His hat was broken, but he received no serious injury. I must say this is a very unusual occurrence, for even in times of great excitement the populace in Ireland treat medical practitioners with the greatest courtesy.

Health of Irish Cities.

The following death-rates show that Cork and Waterford are in a healthy condition:—Belfast, 27·1 per 1000; Limerick, 26·7; Dublin, 24·3; Cork, 18·0; and Waterford, 10·0.

Out-door Musical Promenades for the Working Classes of Cork.

The Mayor of Cork has taken an important step towards procuring healthful amusement for his poorer fellow citizens. Through his instrumentality an Amusements Committee has been formed for the purpose of providing bands to play in the evening in the beautiful suburbs surrounding Cork. Captain Adam, Band President of the 1st South Lancashire, wrote to say that the band of his regiment, with the entire approval of the officers, proposed to give a military concert in one of the city halls for the purpose of raising a fund in aid of the Mayor's project. This generous offer was gladly accepted, and a strong inducement will be held out to the working classes to enjoy the fresh air.

The Disappearance of Typhus Fever in Belfast: a Correction.

In the report on the health of the city of Belfast for 1894 in our last issue (p. 117) it is said that "typhoid" fever is dying out; this should be *typhus* fever.

Irish Workhouses and the Irish Medical Association.

I understand that the Local Government Board has sent circulars to the various boards of guardians, asking for information in reference to the serious allegations made by Sir Philip Smyly, M.D., and Mr. W. J. Hepburn, F.R.C.S. Edin. (the chairman and honorary secretary of the Irish Medical Association), relative to the condition of Irish workhouses. The committee appointed by the Belfast board of guardians to look into this matter reported that, as a result of their investigations these complaints did not apply to the Belfast Workhouse. The nursing staff, they say, is ample and efficient; the food is of excellent quality, and is varied and suitable for different ailments under treatment; the beds are of the newest and most improved description for infirmary and hospital use; and the sanitation and ventilation are both good. The medical officers have no suggestions to submit at present, as all their previous recommendations have been carried out. The committee add that they regret that the allegations should have received so much publicity in view of the fact that the workhouses concerned are not indicated. At a meeting of the Lisburn board of guardians Dr. Mackenzie, medical officer, reported on July 9th in reference to the condition of the workhouse and inmates, in accordance with the desire of the Local Government Board. The report was generally favourable, but the medical officer stated that the diet of the inmates was insufficient and would require revision. One of the guardians present said he was astonished to learn that yellow Indian meal, which the farmers gave to their cattle, was one of the articles of diet. He disapproved of this, and thought with Dr. Mackenzie there should be a change. The report was referred to the House Visiting Committee.—The committee appointed by the board of guardians overseeing the Ballymoney Workhouse handed in a report stating that the house was in a satisfactory condition, with which the medical officer concurred, and that the remarks of the Irish Medical Association did not in any way apply to their institution.—Dr. Fleming, medical attendant at the Omagh Workhouse, reported to the guardians, in reply to the Government Board Circular, that the nursing and caretaking of the patients in the infirmary was insufficient. There are six wards in the infirmary proper and two large ones in the main body of the house all under the care of one nurse. He recommended the employment of an assistant nurse under the supervision of the present one, whose health is endangered by hard work and confinement. He approved of the food as being fair.

Proposed Extension of Belfast Boundary.

It is stated that the Corporation of the City of Belfast intend to have an Act of Parliament introduced during the next Parliamentary session in order to extend the borough boundary so as to take in the area embraced within the Parliamentary boundary. One great advantage of this extension will be that certain districts in which there is at present a defective sanitary arrangement will be properly drained. The Ligoniel suburb is at present in a most unsatisfactory condition, and in the east side of the city the Connswater River is in a deplorable state. Both these areas would be made right under this new scheme.

Portrush Waterworks.

The Local Government Board have sanctioned a loan of £2000 for the improvement of these waterworks. It is hoped that the proposed changes in these works will give a water-supply that both in quantity and quality will be sufficient for such a popular and rapidly-growing seaside resort as Portrush now is.

Death of Mr. English, of Keady, co. Armagh.

I regret to have to announce the death of Mr. English, at his father's residence, Keady, co. Armagh, of pneumonia, on July 14th. He had been in failing health for some time. Mr. English was a Licentiate of the Royal Colleges of Physicians and Surgeons, Edinburgh. He was a young medical man, greatly liked.

Cork Societies' Medical Officers' Indemnity Fund.

Mr. Donovan, the honorary secretary of the above fund, has received £10 from the Yorkshire Branch of the British Medical Association.

Mr. Joseph Edward Kenny, L.R.C.P., L.R.C.S. Edin., L.A.H. Dub., the newly elected member of Parliament for the College Green division of Dublin, is the coroner for the city of Dublin.

(FROM OUR OWN CORRESPONDENT.)

Chronic Poisoning by Coffee.

DR. GILLES DE LA TOURETTE[1] has rendered useful service by reminding the profession of the possibility of toxic symptoms following the inordinate ingestion of coffee. No mention is made of this danger in standard works on medicine. Taking into account, however, the growing popularity of coffee drinking amongst the "upper ten" and their close imitators "the middle million," it is important that a habit which in moderation is in nowise hurtful, but in excess may act as a disturbing factor, should be strictly regulated. Dr. Gilles de la Tourette tells us that chronic coffee poisoning is almost always mistaken for the troubles engendered by the abuse of alcohol. In both cases the stomach and the nervous system bear the brunt of the attack. In effect, caffeic and alcoholic gastritis are nearly identical as to their symptoms—morning vomiting of glairy mucus (*pituites*), pain in the pit of the stomach, thickly-coated tongue, and loss of appetite. The disgust excited by even the idea of solid food is such that these patients eat nothing else but bread soaked in their poison—coffee. There supervene then nausea, vomiting, and painful acid eructations, and

[1] Société Médicale des Hôpitaux, July 5th.

Digitized by Google

the sufferer finally becomes a victim to caffeic cachexia. The circulatory system becomes in its turn attacked, the pulse being slowed to a marked extent. Insomnia is common, and if sleep persist it is disturbed by dreams of a terrifying or professional nature, recalling the nervous disturbance met with in alcoholism. The resemblance is rendered closer by the existence of marked tremor of the muscles of both extremities, and a fibrillar trembling of the tongue muscles, which may extend to the facial muscles. Cramps, often very painful, of the thigh and calf muscles are frequently noted. In certain patients sensibility is diminished, but the reflexes generally remain normal. Paralyses have not yet been seen. The above-mentioned symptoms are not persistent, the suppression of coffee sufficing to bring about their prompt disappearance. It would seem that elimination was in this case more rapid than in the case of alcohol, for suppression is followed by improvement more quickly in one instance than in the other. The abuse of coffee by children has in several instances determined an arrest of development. It is not often that children make an immoderate use of coffee in England, but the same cannot certainly be said of tea, the alkaloid of which is identical with that of coffee. English parents would do well to restrict the supply of tea to children. Neglect of this rule is, I suspect, responsible for many digestive and nervous troubles, the origin of which is vainly sought by the puzzled family medical attendant.

The President of the Republic at the Hôtel-Dieu.

M. Félix Faure has signalised his tenure of office by frequent visits to the Paris hospitals, where his affability has rendered him most popular amongst both patients and students. His stature has, during these friendly visits, generally sufficed to single him out when surrounded by our *confrères*. A few weeks ago, however, when visiting the St. Louis Hospital he had to "take a back seat" in this respect, for he was accompanied by the tallest of French hospital surgeons, M. Marchand, and their appearance side by side was greeted by an amused laugh. On Thursday last the popular Chief of the State inspected the wards of the Hôtel-Dieu and afterwards addressed the entire *personnel* in the courtyard in the following terms :—

"Je ne veux pas quitter l'Hôtel-Dieu sans remercier les chefs de service, les savants médecins, les internes, les sœurs, les infirmiers, tous ceux, en un mot, qui se dévouent, dans cette maison de la souffrance, au service des malheureux. Vous avez pu voir que je m'informe fréquemment, auprès des malades, de leur état et des soins qui leur sont donnés. Ils sont unanimes à reconnaitre les délicates attentions dont vous les entourez. Je suis heureux de me faire leur organe et de vous remercier tous, en leur nom et au nom de la patrie. Comme chef de l'État, je tiens à vous dire combien vos services sont appréciés, combien nous vous en sommes reconnaissants. J'ai voulu venir à l'Hôtel-Dieu à la veille de notre fête nationale, parce qu'il me semble que d'ici je m'adresse à tout le corps médical de Paris et que le lieu était bien choisi pour remettre les récompenses accordées à l'occasion du 14 juillet. Vos médecins recevront leurs décorations dans cette maison, dans ce jardin, comme des soldats reçoivent le ruban sur le champ de bataille, comme des chefs au milieu de leurs troupes."

He then affixed to the coat of Professor Tillaux the Cross of Commander of the Legion of Honour, and handed the Cross of Officer of the same Order to Dr. Nicaise, surgeon of Laënnec Hospital, and Dr. Constantin Paul, physician to the Charité Hospital. On Dr. Deleus, surgeon to the Lariboisière Hospital, Dr. Ferrand, physician to the Hôtel-Dieu, Dr. Landrieux, physician to Lariboisière Hospital, and Dr. Kirmisson, surgeon to the Hospice des Enfants Assistés, he conferred the Cross of Chevalier of the Order. The President did not forget the more humble contributors to the relief of human suffering, for he distributed amongst several nurses silver and bronze medals. The interesting ceremony ended by a vote of thanks to M. Félix Faure, proposed by Dr. Peyron, director of the Assistance Publique.

Price of Tobacco to Hospital Patients.

The Minister of Finance has just decreed that the fragrant weed shall be supplied to the in-patients of French hospitals at the under-mentioned rate :—

Tobacco for smoking purposes,	1½ franc the kilogramme.
,, ,, snuff	ditto.
,, ,, chewing	2 francs the kilogramme.

We may well echo the expression of surprise uttered by the *Bulletin Médicale* at the toleration of chewing in the wards of hospitals, such a disgusting practice being obviously incompatible with the maintenance of that state of cleanliness that should obtain in all nosocomial establishments.

A Sign of the Times.

The *Union Médicale* informs us that it is the intention of the *Assistance Publique* to provide at each Paris hospital for the convenience of students accommodation for the storing of bicycles. If the current continues in the same direction we may soon expect to see hospital physicians and surgeons alight at the doors of these establishments not from their carriages, as at present, but from their cycles.

The French Army.

Of 320,048 young men called upon to serve in the army in 1894, 26,081 were declared unfit for service. During the same year 365 soldiers were discharged because of maladies or infirmities contracted during their term of service, whilst no fewer than 11,807 were in like manner discharged on account of ailments having no connexion with the exigencies of their military duties.

July 16th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

A Blind Graduate.

AN incident not less touching than interesting occurred at the graduation ceremony held the other day at the Istituto di Studi Superiori in Florence. A young gentleman, Signor Luigi Ansaldi, of Rocca Scrivia, blind from birth, took his degree in the department of Literature and Philosophy, after a brilliant course of study in which he won the admiration and esteem of teachers and class-fellows alike. His graduation thesis was a kind *apologia pro vitâ suâ*, entitled "Compensazioni dei Sensi nei Ciechi" (Compensations in the Senses of the Blind). It was an acute and well-thought-out monograph conveyed in excellent style, and was pronounced by the "Commissione di Professori" (examining professors) to be an important contribution to the methods already in use for aiding the moral and intellectual culture of the blind. In fact, on the motion of his Excellency Signor Pasquale Villari, sometime Minister of Public Instruction (the well-known author of the "Lives of Machiavelli and Savonarola"), it was recommended by the Istituto di Studi Superiori for the honour of publication. One of the medical faculty said of it: "E lavoro fisico-psicologico di grande importanza e affatto nuovo" (It is a physico-psychological work of great importance and quite original). Needless to say that Signor Ansaldi received an "ovation" from his class-fellows of all faculties as well as from the general public.

Heat and Snake-bite.

The excessive heat prevailing these last few weeks throughout the kingdom has had one remarkable effect—to increase the virulence of snake-bite and the mortality thence arising. This is a very common lesion in Italy, where so many of the agricultural poor are employed in the *macchie*, or tracts of stunted forest growth, mainly in gathering fuel for the charcoal burners. As a rule the vipers with which these places abound are not deadly—at least, the wounds they inflict are nearly always susceptible of a few days' cure in the local hospital. With the intense heat, however, that since the middle of last month has made itself felt throughout the peninsula a distinct exacerbation of the lesion has declared itself, and cases of death have been so common, particularly in the Alta Italia, as to engage the serious attention of practitioners. On the 13th inst. (I hear from Brescia) a youth of fifteen was bitten on the foot by a viper at Lumezzano, and in a few hours the familiar symptoms of virulent snake-bite (swelling, pain, and ultimately coma) developed themselves, and he died in violent convulsions—all medical aid notwithstanding.

The Sale of Mushrooms.

Poisoning of another kind, still more frequent, is that from the use of mushrooms, particularly those which, in the dry state, are hawked about by the so-called "vivenditori ambulanti." A municipal edict has just been issued to check this constantly recurring calamity at its source, and accordingly fresh mushrooms are allowed to be brought into the city only at certain fixed hours and at certain gates, where sanitary inspection is at once put in practice on them. Even after their being passed as belonging to the edible kind, the mushrooms thence consigned to the dealers' stores are once more subjected to expert examination, and their sale is limited to certain officially permitted quarters—that is, where the sanitary authority has stations. Hawking them about in the thoroughfares and by-streets is a penal offence.

Digitized by Google

Indeed, the sale of them is allowed only by special licence. This is a most salutary regulation, to be applied (let us hope) to other articles of food hardly less dangerous when vended by irresponsible dealers.

July 16th

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Female Physicians and Pharmaceutists.

SOME weeks ago Miss Possaner, a lady who graduated in medicine at Geneva and is at present practising as "hospitant" in the obstetrical clinic of Professor Schanta, petitioned the Austrian Ministry for permission to practise in Vienna. Her request was refused, but, on the other hand, Mrs. Kerschbaumer was allowed some years ago to establish an ophthalmological home in Salzburg, where she carries on a practice in partnership with her husband, who is a physician. Several women have also received appointments as physicians in Bosnia, where the female portion of the population decline to be examined by a medical man. Although, according to the new sanitary law, every municipality is obliged to pay a fixed salary, complaints of the dearth of medical men are nevertheless made in some districts, because not every physician is willing to settle down in a dull country life, where he is surrounded by rustic prejudices and where his annual income hardly exceeds £80. The admission of women to medical practice is, therefore, an urgent necessity. The Hungarian Ministry is inclined to appoint women as pharmaceutists, and the majority of the pharmaceutical profession is in no way opposed to the innovation, for the new regulations as to study have caused a great want of assistants in this country.

Legal Penalties for Medical Negligence.

The Vienna Medical Chamber at the present moment has the following question under its consideration. A poor law medical officer having been called to see a man who had fallen ill with gastric symptoms he diagnosed acute alcoholism without making any examination, and prescribed soda-water with cold cataplasms. The condition of the patient became worse and another practitioner who was sent for found him unconscious and apparently in a fit of apoplexy. The patient died, and a charge of causing bodily harm was brought against the original medical attendant, in accordance with paragraph 431 of the Penal Law. The expert who gave evidence explained that although a careful examination might not have led to a different diagnosis, there was, in his opinion, a neglect of duty, for the poor law medical officer had not fulfilled his obligation of trying to find out the cause of the illness. The accused was fined £5 with twenty hours' imprisonment, a sentence which was confirmed by the Court of Appeal. By this decision the court declared that the neglect of examination had caused no injury to the patient, but that the medical officer ought to have known that his conduct might endanger life. This result has caused a great sensation throughout the profession of medicine, for it throws serious obstacles in the way of medical treatment. Who would perform a surgical operation if the above-quoted paragraph be interpreted in this manner? Every operative procedure exposes the patient to danger, and the surgeon will have to justify himself even in the cases where operations are successful. The law punishes the infliction of bodily injury by a medical man's ignorance or negligence, but does not punish the endangering of the patient's life or health when caused either by medical treatment or by neglect. The Medical Chamber has taken up this question, and at the last meeting a member brought in a motion referring to the provisions of the law as regards offences committed by medical men. Paragraph 431 is inapplicable hereto, for it imposes penalties amounting to £40 fine or three months' imprisonment, whereas paragraph 358 imposes only a fine of £40 in the case of actual injury or death due to neglect. The Chamber adopted this motion and will take steps to defend the profession against decisions which are not in conformity with the spirit of the law.

Loretin.

Dr. Trnka has published in the *Wiener Medicinische Wochenschrift* a paper on the utility of loretin in surgical practice. It is an inodorous, sulphur-coloured, mealy powder, producing neither local nor general toxic effects. It is employed instead of iodoform, for it causes but trifling granulation, limits secretion, and is also cheaper than iodoform. A compound of equal parts of loretin and calcined magnesia is well adapted for favouring primary healing of wounds; a solution of five parts of loretin with two parts of tragacanth and glycerine in one hundred parts of water possesses the same quality as collodion of depositing a filmy coating.

Professor Hering.

In Professor Hering, who has been elected successor to the late Professor Ludwig, the German University of Prague loses one of its best known members, and Austria its most able physiologist. I need mention only his ingenious theory of colours wherein he explained that the action of seeing is an expression for a tissue change in the visual purple, his experiments on anomalous contraction, and his interesting objections against the psycho-physical law of Fechner. He felt himself slighted because he did not succeed in obtaining the object of his ambition—the chair of the late Professor Brücke. At that time the Government gave him fair hopes of being appointed to a second chair of Physiology which was to be established in Vienna. Professor Hering and the late Professor Fleischl have been the most celebrated followers of the far-famed Brücke, to whom physiology owes so much.

July 14th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera in the Quarantine Camp.

SOME special Providence seems to have averted an explosion of cholera in the Holy Places, and we no longer hear of the dropping cases which preceded the feast days. Dr. Gauthier is now in charge of the pathological and bacteriological investigations into the sick and dead at the Tor quarantine camp, and it would seem from his reports that matters have been placed upon a more scientific basis than in former years. He reports on June 18th that he has made bacteriological researches in the case of eighteen suspected hospital patients suffering from diarrhœa, but that in every instance the result was negative. Fortunately, now, however, it is the rule, and not the exception, to conduct necropsies, and by this means two cases of certain cholera were found, though there is no record of these two men having been under any medical treatment before death. Both men came from the same steamer. The more typical case of the two showed great sinking in of the eyes without emaciation, intense congestion of the abdominal contents, enlarged liver and spleen, with bladder retracted behind the pubes and containing no urine. The stomach and small and large intestines were full of liquid holding white flakes in suspension, and this liquid eventually showed under the microscope rods, micrococci, staphylococci, and eventually comma bacilli upon all the cultures of peptone.

The Origin of Massage.

An annotation in THE LANCET of June 22nd invites search for the derivation of this word and the origin of the custom. At present I think we can hardly do better than accept the Greek μάσσειν, to knead, connected with the Sanskrit *mack*, to pound. The only Arabic word in Turkey or Egypt for massage after the bath or elsewhere is *takbees*, from the root *kubas*. There is an Arabic word *muss'h*, but it means to wipe away dust, and is never used for rubbing or kneading. Lastly, the operation of cracking the bather's joints, which occurs after the hot bath and before the muscles are kneaded, is called *tuck tuckah*. Medical rubbing has been used in Egypt for centuries, but whether before Roman times I do not know. Among the curiosities of Old Cairo are occasionally found stones which were used for massage. Visitors to Pompeii will call to mind a picture in the bath of a person undergoing massage, and readers of Cicero may remember his friend Asclepiades of Bithynia, who, after having learnt his profession at Alexandria under the best teachers of the day, settled in Rome in the beginning of the first century B.C.,

Digitized by Google

and there introduced into medical practice both hydrotherapeutics and massage.

The Tourah Prison.

The chief prison in Egypt for male hard labour convicts is at Tourah, about eight miles south of Cairo, where the adjacent quarries, which once furnished limestone to the builders of the Great Pyramids, supply unlimited scope for labour six days a week. There are 950 convicts, and though 100 of them are "lifers," there are others whose term is only for six months. Strict discipline is maintained by sixty-five warders who are unarmed and do not carry even a stick or whip; but by night there are nine sentries and by day there are four, who patrol the roof and the outside of the prison, and who know how to use their loaded rifles with deadly aim. These sentries are blacks from the Equatorial provinces, and have prevented more than one attempted escape. Nearly all the convicts are natives of Egypt, the blacks only supplying five per thousand and the Nubians averaging only two per thousand. Any extra bad characters among the convicts, such as the ringleaders of attempted revolt or escape, are locked up at night in solitary cells to lessen their chances of contaminating their fellows. As a whole the convicts are by no means of a ruffianly type and their physiognomies are very like those of the ordinary peasant. In this country, where crime is at such a minimum and where even the lunatics are as quiet as sheep, it is not too much to hope that education and improved environment may one day do much to improve the lot of the townsfolk from whom the convicts are mostly drawn. The "ticket-of-leave" system has not yet been introduced into Egypt, and would certainly be worth a trial, for at present there is very little incentive to well-conducted convicts to lead a peaceful, hard-working life within the prison bounds. Every visitor cannot fail to be struck with the very healthy, well-fed appearance of the prisoners, and on inquiry I was told that there were only fourteen on the sick-list. The regulation space for the dormitories is a little over 700 cubic feet. A hospital consisting of two separate pavilions has just been built near the prison containing accommodation for twenty-four ordinary sick and forty infectious cases. Tourah prison went through a sad experience some years ago when its inmates were ravaged by typhus and relapsing fevers, and the remembrance of this epidemic has doubtless occasioned the remodelling of the cells and the present very satisfactory condition of the convicts. One man was pointed out to me as having killed his father, mother, wife, and children, and it might be easy to prove that he was suffering from homicidal mania, but we are not yet civilised enough to have a home for the criminal insane, and I doubt if he could be more profitably employed than in hewing stone and drawing water under medical supervision.

Detection of Criminals.

In Alexandria a special staff of European constables is being trained to apply the Bertillon method to prisoners, and so far good reports have been received. It may, perhaps, be doubted whether the Egyptian is a sufficiently accurate individual to profit by a careful series of measurements. On the other hand, it must not be forgotten that photographs of criminals are useless for the untrained eye of the native policeman.

Hospital for Infectious Diseases.

The first hospital devoted entirely to the treatment of infectious disease is now in full working order in the Abbassiyeh Desert, near Cairo, and is a natural development of the tents which have been in use until this year. The ground consists of several acres of desert, levelled and walled in, and roads to it are now being made by a gang of chronic lunatics from the neighbouring asylum. There are five detached buildings on the pavilion system for typhus fever, small-pox, disinfection, necropsies, &c. There are twenty-six beds and unlimited space for tents if that number should be exceeded. The disinfecting block is under the charge of a German engineer, who lives on the spot with the native doctor. Infectious clothing is submitted to dry heat (230° F.) for three hours in two stoves, and a bath-room and douche for the attendants have not been forgotten. The laundry is fitted up with English machines, and the store-rooms are a model of neatness and complete in every respect. The young native house physician is just recovering from an attack of typhus fever.

Cairo, July 1st.

Obituary.

CORNELIUS S. HALL, M.R.C.S. ENG., L.S.A.

THE death is announced, at his residence in Carlisle, on July 6th, of Mr. Cornelius S. Hall, one of the oldest practitioners in that city and one holding many appointments. After being "apprenticed" to a country practitioner he studied at the London Hospital, and during his course was one of the medical visitors appointed by Government in the cholera plague of 1854. He then volunteered for service in the Crimea, where he had for one "chum" the present surgeon to the Queen in Scotland, Dr. Patrick Heron Watson. On his return to England he spent eighteen months in Manchester, whence he moved to Carlisle, where he at once obtained an appointment at the Dispensary and Fever Hospital. In 1862 he became factory surgeon, in 1864 medical officer to the workhouse hospital, in 1875 medical officer to the Carlisle rural district authority, and in 1888 surgeon to the Police Force. He always took a great interest in Volunteer movements, and attained the rank of brigade-surgeon-lieutenant-colonel. Of scientific subjects he was especially fond, botany, geology, meteorology, and microscopy being special hobbies. He was president of the Carlisle Microscopical Society for many years, and Fellow of the Royal Microscopical Society. His papers on the Treatment and Burial of the Dead; Noise, Silence, and Sound; Pasteur and his Work, &c., were of great interest and were quoted by newspapers all over the country. Workhouse nursing was a subject needing special reformation, and into this he threw his whole heart. A paper on Workhouse Nursing was eagerly sought by many interested in the work and gave quite an impetus to hospital nursing. He was a man of wide sympathies and liberal-minded in all things. As a worker he was enthusiastic and accurate; no trouble was too great. He was universally respected and beloved, and his death will make a void not easily filled.

WILLIAM CROUDSON BARNISH, M.R.C.S. ENG., L.S.A.,

MEDICAL OFFICER OF HEALTH, WIGAN.

ON June 27th the profession lost a noble member and Wigan an efficient, courteous, discriminating, and obliging health officer. William Croudson Barnish was an excellent type of general practitioner and one who was able to discharge his duties as health officer without friction with his brother practitioners or clashing in an unreasonable way with his patients. Mr. Barnish in early life assisted his father, who was a chemist in the town; but his love of chemistry and natural science led him, on the advice of his brother-in-law (the late Dr. Birkenhead, who was afterwards Professor of Chemistry in the Liverpool School), to study medicine. He accordingly entered at the Manchester School of Medicine and qualified as M.R.C.S. Eng. and L.S.A. in 1868. After holding a couple of house surgeoncies he joined the late Mr. Fisher, who had an extensive surgical practice in Wigan, and the partnership lasted till Mr. Fisher's death some years ago. For twenty-five years Mr. Barnish was medical officer of health for Wigan. He was a genuine health officer, and numerous are the improvements which he has effected. Several epidemics of small-pox, typhus fever, and typhoid fever he was able to combat, and during the past ten years effected many changes, such as the abolition of the old small-pox hospital and the building of a new sanatorium, which is a model for a town of the size of Wigan. At the time of his death he was senior honorary medical officer to the Royal Albert Edward Infirmary, and the governors, to mark their sense of appreciation, two years ago made him one of its vice-presidents. He also gave numerous ambulance lectures to various classes, and latterly acted as examiner. Mr. Barnish was beloved by his patients and by all with whom he came in contact. This year in March he contracted influenza, which he appeared not to be able to throw off, and although he kept to his work up to within two months of his death his friends could see he had not his usual vivacity. Yet without murmur he stuck to his post till rest was absolutely necessary, and he was ordered away for a time, but this brought no relief to the cardiac failure from which he suffered; he returned

Digitized by Google

home without improvement, bore his affliction manfully, and passed quietly away on the date above mentioned at the age of fifty-five years, leaving a sorrowing widow and six children to mourn their loss. He was interred in the family vault at the Wigan Parish Church on July 1st, the funeral being attended by his relatives, professional brethren, and members of the Sanitary Committee, of the Corporation, and of the Infirmary Board of Management.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Elias Rodriguez, Professor of Therapeutics and Forensic Medicine in Carácas; and Dr. José Maria Teixeira, Professor of Pharmacology and Therapeutics in the University of Rio de Janeiro.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen were, at the quarterly meeting of the Council on Thursday, July 11th, elected to the various offices for the ensuing collegiate year:—

Hunterian Professors.—Charles Steward, Conservator of the College Museum, M.R.C.S. Eng. (St. Thomas's Hospital); subject of lecture not stated.—John Alfred Coutts, M.B. Cantab., M.R.C.S. Eng., (St. George's Hospital), on Infantile Syphilis.—Leonard Erskine Hill, M.B. Lond., M.R.C.S. Eng. (University College Hospital), on Cerebral Pressure and the Cerebral Circulation.

Arris and Gale Lecturer.—Ernest Henry Starling, M.D. & B.S. Lond., M.R.C.S. Eng. (Guy's Hospital), on the Physiological Causation of Dropsy.

Erasmus Wilson Lecturer.—Walter George Spencer, F.R.C.S. Eng., M.B. and B.S. Lond. (Westminster Hospital), on the General Pathology of Bone.

Pathological Curator.—James Henry Targett, F.R.C.S. Eng., M.B., B.S. and M.S. Lond. (Guy's Hospital), re-elected.

Anatomical Assistant in the Museum.—Richard Higgins Burne, B.A. Oxon., re-elected.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bonn:* Professor Mikulicz of Breslau, who was invited to succeed Professor Trendelenburg in the Chair of Surgery, having declined to migrate, the post has been offered to Dr. Schede, director of the Surgical Side of the Eppendorf General Hospital, Hamburg.—*Tubingen:* Dr. Henke, Professor of Anatomy and Director of the Anatomical Institute, is retiring. Professor Curtius of Kiel has been appointed to the Chair of Chemistry, in succession to Dr. Lothar von Meyer.

DR. D. H. ATTFIELD, M.A. Cantab., English Quarantine Medical Officer of the Egyptian Government at Suez, who last year during the Mecca Pilgrimage months filled the post of subdirector of the quarantine camp at El Tor, has this year, during the similar period, been appointed the chief director of the extra Egyptian Camp at Ras Mallap. Dr. Attfield is the son of Professor Attfield, the editor of the British Pharmacopœia.

ROYAL COLLEGE OF SURGEONS IN IRELAND—Prize List, Summer Session, 1895:—The Barker Anatomical Prizes: N. H. Alcock and C. J. Patten (equal), £26 5*s.* each; W. J. Sweeny, special prize, £15 15*s.* The Carmichael Scholarship: F. J. Palmer, £15. The Theory and Practice of Surgery: L. McDowell, gold medal; G. A. Robinson, silver medal; Miss C. L. Williams, certificate. Practical Histology: D. Hadden, first prize; H. Hall, second prize. Practical Chemistry: P. A. Frazer, first prize; C. C. Meek and W. J. Anglim (equal), second prizes. Public Health and Forensic Medicine: A. I. Eades, first prize; Miss C. L. Williams, second prize. Materia Medica: R. H. D. Pope, first prize; G. R. McDonald, second prize. Practical Pharmacy: S. R. Godkin, first prize; M. Gavin, second prize. Biology: M. Gavin, first prize; W. McLorinan and W. J. Anglim (equal), second prizes. The preliminary Examination for the commencement of medical study of the Royal Colleges of Physicians and Surgeons in Ireland for sessions 1895–96 will be held on Tuesday and Wednesday, Oct. 1st and 2nd, 1895. Prospectuses can be had on application.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the half-year ending June, which was given in the number of the 29th ult., completed the first volume of the year 1895. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1895 are now ready. Bound in cloth, gilt lettered, price 18*s*.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s*.

To be obtained on application to the Manager, accompanied by remittance.

THE LANCET AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

THE RULE AS TO CALLING IN LONDON.

Sigma.—We think that a new comer in London should call on those in practice in the neighbourhood. London is in this respect a place by itself. It is impossible that a medical man can know of the arrival of a new comer as he would in a country town.

"LYSIDINE."

To the Editors of THE LANCET.

SIRS,—In answer to "Subscriber's" inquiry, I beg to inform him that trials made with this drug in Germany have revealed no disturbing symptoms of any kind. As to the cure being temporary or permanent, enough trials of the drug have not yet been made to enable one to say with certainty. I am, Sirs, yours faithfully,

July 16th, 1895. H.

*** The agents for Lysidine are the Jeyes' Sanitary Compounds Co., Ltd., who will give any information in their power concerning the remedy.—ED. L.

MEDICAL DIRECTORS OF COMMERCIAL COMPANIES FOR THE SALE OF ANTISEPTICS.

OUR attention has been directed to the name of a medical man as one of the directors of a company for the sale of a well-known disinfectant and germicide. It occurs on a circular inviting applications for shares. We are practically invited to express an opinion on the fitness of a medical man in such a position. It seems hard that medical men, who often sorely need to have their strictly professional income supplemented by other sources of profit, should be hindered from holding an office of this sort; but on closely considering the question we cannot fail to see the advantage of their perfect freedom. It is not in the interest of the company that they should be on the directorate; for the value of their medical judgment will be so far reduced in the public mind by their supposed commercial interest. And it is not in the interest of the medical man himself that he should be warped in any degree from perfect impartiality of judgment in the preference for antiseptics by such considerations. It is conceivable, of course, that a medical man might be perfectly efficient as a director though interested, and that he might be sincere, too; but, looking at the matter from a professional point of view and in the light of common-sense, our opinion is against the tenure of such offices by members of the profession.

H. H.—Will our correspondent kindly state his question at greater length and detail, explaining more exactly the pecuniary relations existing between himself and another?

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—Will you allow me as a layman to contribute a few lines on the interesting question now under discussion in your columns? The difficulty respecting the use of the term "doctor" arises surely from what logicians call the equivocal or ambiguous character of the word. The term "doctor" is used (1) to denote a person professionally engaged in the practice of medicine—in the same manner that the term solicitor is used of those professionally engaged in certain legal work; and (2) as a title, signifying that the holder has been granted the degree of Doctor in one of the Faculties by some University (or by the Archbishop of Canterbury). This title belongs to many lawyers, clergymen, and scientific men, in company with a large number of medical men who are "doctors" in the former sense. As a layman I have made it a rule—sometimes, I fear, at the risk of seeming discourteous—to restrict the use of the title as a form of address to the actual possessors of a Doctor's degree, and consistently with this practice I should refrain, rightly or wrongly, from addressing as Doctor the B.D., the B.C.L., and the M.B. So far for the use of the word as a title. Now it is not customary in England for men to be addressed in ordinary intercourse by the name of the profession which they follow. We frequently say, "Send for my solicitor," "Send for my surgeon," "Send for my dentist," but we should never think of addressing our professional adviser as "Solicitor Jones," "Dentist Smith," or even as "Surgeon Brown," unless "Surgeon" were used as a title of military rank. Why, then, should we make an exception in the case of our medical attendant? In your issue of the 29th ult. your correspondent "Not L.S.A." asks why, if a patient may say, "Send for my doctor," may he not also say, "Good morning, Doctor." My answer is that there is no objection, provided that he uses the word doctor in the same sense in both instances; as a matter of fact, the word is used in two totally different significations—in the former case doctor (small *d*) is simply equivalent to "medical man," while in the latter case Doctor (capital *d*) is used as a title or prefix (analogous to "Colonel" or "Baron"), to which certain University graduates are alone entitled. If the word "doctor" is used in the same sense in both cases, the substitution of a synonym in either case should not affect the meaning. For "doctor" let us, then, substitute "medical man." Now in the former case the meaning is unchanged, "Send for my medical man"; but the substitution in the latter case presents a curious and unusual form of salutation, "Good morning, medical man." Can a better proof be required of the ambiguous use of the word, which I venture to suggest is the *fons et origo* of the difficulty?—I am, Sirs, your obedient servant,

New Oxford and Cambridge Club. R. B. F.

To the Editors of THE LANCET.

SIRS,—From the replies to Dr. Donovan's letter it is evident some Licentiates of the Society of Apothecaries are quite satisfied with the diploma of that body and believe it to be an exceptionally good one. What my own opinion on this matter may be, as it is not always easy to speak or write the truth without being highly offensive, I will not venture to state; yet it is beyond doubt there are a goodly number who hold the diploma of an apothecary who are absolutely ashamed of it and who strictly avoid mention of it on door-plate or certificate. These men usurp the titles conferred by universities and colleges, and unblushingly pose before the public as genuine medical men and physicians. It seems that if a man is on the Register, no matter what his qualification may be, he is in a position to filch what diploma or title he chooses without infringing on the Medical Act, as this simply deals with the unregistered persons who, without a registrable qualification, "makes use of any title, name, &c." It becomes more evident daily that it is long past time the Medical Council took up the subject of medical titles and made it easy for the public to distinguish an apothecary from a physician and a "doctor" from either. I can quite conceive how difficult it is for the Medical Council to enter on a campaign on titles. The Council is composed of the consulting members of our profession mostly, if not altogether. These depend on the general practitioner for consultations. Therefore, for any consultant to initiate a campaign on titles would undoubtedly place him in a position with a large number of his medical supporters that may safely be described as awkward. Self-interest shelves the question, as it does a host of others, and thus the apothecary will continue to pose as a Doctor of Medicine, or a physician, or both, until by some means it becomes a penal offence to practise medicine under false pretences.—I am, Sirs, yours faithfully,

July 16th, 1895. A SPADE.

To the Editors of THE LANCET.

SIRS,—With regard to this much-vexed question I believe it has been pointed out in your columns, not once but many times, that the title of "doctor" when placed upon a brass plate or card implies that such individual is nothing more or less than a Doctor of Medicine, and the same with a practitioner who holds the diploma of a Royal College of Surgeons; that individual alone is entitled to term himself surgeon. Or the practitioner who holds the diploma of the Royal College of Physicians; such individual is entitled to term himself physician. Therefore it is evident that a Licentiate of the Society of Apothecaries cannot be anything else but an apothecary. When the licence of apothecary was converted into a double qualification it was then distinctly pointed out by certain authorities upon the Medical Council that it would be the means of creating two classes of medical and surgical practitioners—viz., the apothecary and the physician and surgeon. I remain, Sirs, yours truly,

July 16th, 1895. L.S.A., LIC. IN MED. AND SURGERY.

To the Editors of THE LANCET.

SIRS,—The perennial question as to whom amongst legally qualified medical men the title of "Dr." belongs has again been opened in your columns. It is not my intention to enter into the discussion, and my only desire in writing is to direct the attention of those interested in the subject to the custom prevailing in Italy, with which I am well acquainted. There all medical men before they are allowed to practise must obtain from one of the numerous universities the degree of, not M.D., but Medico-Chirurgico, which in English is physician and surgeon. Notwithstanding this all these physicians and surgeons call, and are called by everybody, "Dr.," and they would be very much surprised to hear that they have no right to that title. In fact, the usual custom is when signing their names to place the much disputed title before them. Now, I would ask those gentlemen who object to a physician and surgeon in this country using the title, would they also object to his using it in Italy should he set up in practice in a large city there? I am, Sirs, yours truly,

July 6th, 1895. MEDICO-CHIRURGICO.

To the Editors of THE LANCET.

SIRS,—I do not, of course, pretend to understand either Mr. Feeny's English or his code of discussion. His last letter, if it means anything, shows that he is quite in the dark concerning the subject about which he writes. This is surprising; because a man of ordinary perspicacity who has travelled abroad might have been expected to give correct information, instead of simply indulging in personal remarks. I am, Sirs, yours obediently,

Harley-street, W., July 13th, 1895. J. KESER.

To the Editors of THE LANCET.

SIRS,—I have to offer to you and to your readers my apology for having stated that the L S.A. was by right entitled to style himself "Dr." I made the statement on hearsay evidence, and when I did so believed it so thoroughly that I never even thought of there being any necessity for inquiry. I find that I was completely wrong, and unreservedly withdraw my words, which I much regret having written.

I am, Sirs, yours obediently,

July 16th, 1895. NOT L.S.A.

To the Editors of THE LANCET.

SIRS,—Having written in my own name, I decline to answer your correspondents, who are fearless enough to write as they have done whilst hiding behind the hedge of a pseudonym.

I am, Sirs, yours faithfully,

July 15th, 1895. WILLIAM DONOVAN, M.D. Durh., L.R.C.P. Ed.

THE CLIMATE OF THAYETMYO.

To the Editors of THE LANCET.

SIRS,—Would any reader, army medical officer or otherwise, who knows anything of the climate of Thayetmyo, Lower Burma, kindly inform me whether or not it is a very deleterious one for young children, and if so whether there is a salubrious district near to which invalids could be easily removed in case of ill-health? Answers will be esteemed a great favour, as important interests are at stake.

I am, Sirs, yours truly,

Southport, July 17th, 1895. M D.

PUBLIC LECTURES ON PROFESSIONAL SUBJECTS BY MEDICAL MEN.

THE *Cape Argus* contains an abstract of a lecture on the Eye and Eyesight, delivered to the Young Men's Christian Association by Dr. Fismer, a respected practitioner in Cape Town, who affects some special skill in eye disease, and who is also in general practice. Our opinion, which is asked for, must be general. We consider it a point of good taste that a medical man shall do nothing publicly with a mere purpose to advertise his skill or his professional opinions on moot points of practice. We are not disposed to say that a medical man is not to be permitted to give a lecture to young men that might instruct them. This would be a hard rule, which has been often violated by respected practitioners. But his lecture must savour rather of the teacher than the practitioner—must be physiological rather than medical in its drift.

THE MISUSE OF HOSPITALS.

To the Editors of THE LANCET.

SIRS,—The following two cases—and I could speak of many others—may help to throw some light on the above subject.

1. I had arranged to operate upon the child of A. for post-nasal growths. A. is a gentleman living in a good house of, I suppose, £80 or £90 rental, just home from a month's tour in Devonshire with his family. A few days ago I received a letter containing the following words: "On Saturday an old friend of mine, an influential member of the committee of —— —— Hospital, to whom I had spoken about ——'s throat, told me that he had arranged for Dr. —— of —— street to see —— specially at the hospital at 1.30 P.M. on Monday, and if the operation ought to be done at once they would arrange for her reception then and there." The child went, was operated upon, and taken into the hospital.

2. A gentleman of very good position and means, whom I had attended with alcoholic inflammation of the membranes of the cord, with considerable sloughing, but who recovered with a stiffish hip-joint, married again. His wife took him to see the senior surgeon of —— Hospital, who advised him to come in. He did so, was there treated, and on leaving the hospital is under the care of a gentleman educated under the said surgeon.

Cases might be multiplied; but surely it is going a little beyond the very low moral tone prevalent when "an influential member of the committee" becomes little less than a tout for other people's patients.

I am, Sirs, faithfully yours,

July 15th, 1895. A THIRTY YEARS' PRACTITIONER.

LORD BYRON'S LAMENESS.

To the Editors of THE LANCET.

SIRS,—Being much interested in the subject of club-foot, whether congenital or acquired, I should be obliged if you could tell me where I can find out the nature of the deformity from which Lord Byron suffered. In Moore's Life of Byron he says: "By an accident which occurred, it is said, at the time of his birth one of his feet (the right) was twisted out of its natural position, and this defect, chiefly on account of the mechanical contrivances employed to remedy it, was a source of great inconvenience to him. ..... The expedients used were adopted by the advice and under the direction of the celebrated John Hunter, with whom Dr. Livingstone of Aberdeen corresponded on the subject." Can any of this correspondence be unearthed? Or can any of your correspondents who have more advantages of national medical libraries than we have at this end of the world find out for me what the precise nature of the disease was?—I am, Sirs, yours faithfully,

Dunedin, New Zealand, May 22nd, 1895. M.B., C.M.

SANITARY SHIELDS FOR BABIES' FEEDING BOTTLES, &c.

THESE are discs of highly-glazed porcelain, designed to replace the familiar bone shields which are attached to the teats of infants' feeding bottles. The bone shields, even when of good quality, soon become roughened and porous, and are liable to absorb saliva and milk, drawbacks from which the sanitary shields are entirely free. In the artificial feeding of infants thorough cleanliness is indispensable, on which ground the utility of this device is at once apparent. The makers are Messrs. Kennedy and Co., 159, Kingsland-road, London, E.

THE METHODS OF CERTAIN PROVIDENT ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—Whilst in a shop talking to a patient an agent entered, presenting a list of medical names offering professional attendance for three half-pence per week. Without disclosing my identity, I ventured to object to such advantages being offered to any except the working-classes, on which the agent declared that all were fish to his net, even to a man with a rental of £150 per annum. He went on to explain that medical men, like lawyers, were only a "figment," and they were only too glad to accept such emolument. He then paraded the name of a new-comer who had "signed the contract." The agent was evidently prepared to tout to any extent, stating that he would accept the Prince of Wales if willing to join on the same terms.

I am, Sirs, yours faithfully,

July 17th, 1895. MEDICUS.

"ALLEGED TOUTING BY A PUBLIC VACCINATOR."

IN noticing under this title a dispute between a practitioner and the public vaccinator of his neighbourhood we found it our duty upon the facts supplied to us to comment severely upon the public official. We have since, however, received a letter from the public vaccinator's principal, which places a different complexion upon the matter, and we are much obliged to him for it, and we regret that its essential point was not previously perceived. In our former comments we were under the impression that the public vaccinator had acted on his own accord, for it was not previously brought to our notice that his visit had been made only in consequence of representations made to him by the vaccination officer with regard to defaulters. This point was not brought out in any of the previous letters submitted to us. Had it been we should certainly not have used the term "touting" with regard to the public vaccinator's action.

X.H.S.—We consider that our correspondent will be quite right to describe himself in the Medical Directory as a late officer to the institution under its present name.

"THE SKOPTZY."

To the Editors of THE LANCET.

SIRS,—In the Museum of the Royal College of Surgeons (Pathological Series, No. 25) your correspondent will find a dissection of part of the pelvic viscera of an adult member of this sect. The operation was performed in early adult life. The external organs were, as is the custom, entirely removed. In the specimen atrophy of the prostate is well marked, the vasa deferentia are threadlike, and the vesiculæ seminales are without their natural pouchings. The women submit to mutilation of the mammæ. Jules Claretie introduces two members of this sect in one of his works of fiction. Pelikan wrote an important and well-illustrated monograph on the subject — "Gerichtlichmedicinische Untersuchungen über das Skopzenthum in Russland."

I am, Sirs, yours faithfully,

July 15th, 1895. ALBAN DORAN.

THE "SANITAS" POCKET DISINFECTANT.

THIS is an ingenious method of putting up "Sanitas," so as to be conveniently and instantly available for inhalation in an offensive or unwholesome atmosphere. The liquid having been sealed up in small glass bulbs, these are varnished and rolled one by one in cotton-wool, over which a piece of white muslin is tied. The whole is then about the size of a filbert. When required for use a tap on the outside with any hard object breaks the glass bulb, and sufficient "Sanitas" is then liberated to saturate the cotton-wool and muslin, as well as to impart a little to the handkerchief if desired. The broken glass gives no trouble, being retained inside the wrappers, and the agreeable odour of "Sanitas"—suggestive of camphor and peppermint—remains for a considerable time. The manufacturers are the Sanitas Co., Ltd., Three Colt-lane, London, E.

THE TREATMENT OF TRISMUS.

To the Editors of THE LANCET.

SIRS,—Would any of your readers kindly give me any hints as to treatment in the following case?

A man aged thirty-three, saddler, suffers from chronic trismus. Three years previously had sunstroke in West Australia. Since then has had constant grinding of the teeth at night—so much so as to disturb others, although not cognisant of it himself. Nerve sedatives and tonics have been tried, but with no avail. Temporary relief with bromides; symptoms returning with discontinuance of treatment. Blisters and galvanism have also been used, but no relief obtained. General health is always good. I am, Sirs, yours faithfully,

July 13th, 1895. M.R.C.P.I.

POOR-LAW MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—I should feel obliged if you will kindly answer the following:—

1. Would the Local Government Board sanction my appointment as Poor-law medical officer for a few weeks pending permanent appointment being made, having only the surgeon's qualification? 2. When an appointment is made would the Local Government Board sanction my appointment as deputy? I am, Sirs, yours truly,

Wolverhampton, July 15th, 1894. QUÆSITUS.

*** 1. Yes, if appointed by the guardians.—2. The deputy appointment would rest with the guardians.—ED. L.

WANTED, ADVICE ON HEALTH RESORTS.

To the Editors of THE LANCET.

SIRS,—Would any of your readers be kind enough to give me some information as to a good continental health resort where cases of rheumatic neuralgia are benefited? Also as to a good and suitable winter place (not Egypt) for a case of chronic nephritis?

I am, Sirs, yours truly,

July 15th, 1896. O. H.

TRADE **Emol-Keleet:** MARK.

SINCE our first leaflet dealing with Emol-Keleet was issued we have received many encouraging reports of the beneficial effects of this substance in Surgery and Dermatology. It has been used not only for its absorbent, anti-pruritic, and emollient qualities, but also as a diluent for such antiseptic agents as Loretin, Dermatol, Iodoform, Boric Acid, Chrysophanic Acid, Hydro-Naphthol, &c. Owing to the fact that it is a natural powder containing a large proportion of native silicates, Emol-Keleet is chemically stable, and is therefore freely prescribed as a diluent for potent medicinal agents without fear of combination taking place. In addition to these chemical advantages, its soft silky texture, soothing influence, and other physical qualities enhance its healing action.

In a paper reported in the March number of the *Glasgow Medical Journal* Dr. G. A. Turner, President of the Glasgow Obstetrical and Gynæcological Society, speaks very highly of a mixture of Emol-Keleet with Loretin (meta-iodo-ortho oxyquinoline-ana-sulphonic acid) in the treatment of the umbilical cord immediately after birth. The proportions originally suggested for an absorbent antiseptic powder were:

Emol-Keleet, nine parts,
Loretin, one part;

but since then it has been found that 1 or 2 per cent. of the latter body is amply sufficient.

The following paragraph from the paper referred to will show what a wide field exists for the advantageous use of Emol-Keleet with Loretin.

"It has been suggested that Loretin, when mixed with a little magnesia, is well adapted for use as a dusting powder. For such use, undiluted, it would be too expensive, nor is it necessary. It may be used mixed with magnesia, or Fuller's earth, or with the dusting powder, Emol-Keleet, which was recently brought prominently before the profession at the meeting of the British Medical Association at Newcastle-on-Tyne, by a paper read by the president of the Dermatological Section, Dr. Allan Jamieson, of Edinburgh." He concluded that Emol-Keleet as a dusting-powder was a "perfectly innocuous and inoffensive material, therapeutically superior to any previously known."

"A short time ago I wrote Messrs. Burroughs, Wellcome, & Co. of London, making the suggestion that a mixture of Loretin and Emol-Keleet would probably prove a valuable dusting powder for infants. I received a reply, from which the following is an extract: 'The suggestion which was originally made to use magnesia as a diluent of Loretin was made on the grounds that magnesia is so good an absorbent, is comparatively cheap, popular with some continentals in this direction, and very harmless. The suggestion now made by yourself that Emol-Keleet be used as a diluent is, in our judgment, a most admirable one, and one which should have very excellent results.'

"What I have to suggest, then, is that by the use of some such dusting powder as this our treatment of the new-born infant will be brought more into line with present-day antiseptic midwifery and surgery; the common excoriations of the skin surrounding the genital organs, &c., will in great measure be avoided, and all such troublesome complications as excoriations and fungating excrescences of the umbilicus, or ulceration or sloughing of its margin, and erysipelas neonatorum and tetanus neonatorum will be things of the past."

Both Emol-Keelet and Loretin may be obtained from all first-class pharmacists, so that if practitioners prefer to use higher or lower percentages than those mentioned they can easily obtain them by prescriptions.

We append the testimony of a few eminent authorities on Emol-Keleet:—

THE LANCET says:—

"On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in the treatment of cutaneous diseases, &c., and for allaying irritation. We have not examined a more unctuous earth."

BRAITHWAITE'S RETROSPECT OF MEDICINE, says:—

"Emol-Keleet is the most beautiful impalpable mineral powder with which we are acquainted, and promises to supersede all the older forms of dusting powders. Beyond the purely mechanical effect of covering and protecting from friction or irritation the surface to which it is applied, Emol-Keleet is possessed of distinct emollient and soothing properties, as well as being a most efficient anti-pruritic. We have made use of it for some time past in the treatment of eczema, especially in infants and young children, where dry and soothing agents are most desired, and have found it to be a most excellent application in such cases, while the readiness with which it can be used and its absolute freedom from all risks of decomposition, add largely to its value. It has also proved to be of great use in the removal of epidermal concretions such as are seen in eczematous conditions of the palms and soles. We can most confidently recommend it as an addition of great value to the resources of the dermatologist."

The QUARTERLY MEDICAL JOURNAL says:—

"As a dusting powder it has the advantage that when the part to which it has been applied becomes moist, it forms a kind of natural soap, and is free from the 'balling' tendency of many insoluble powders. It forms a pleasant, effective tooth powder, not being liable to scratch the enamel."

The EDINBURGH MEDICAL JOURNAL:—

"Having ourselves extensively tested it, we can most warmly recommend it."

The DUBLIN MEDICAL JOURNAL says:—

"An excellent topical application after vaccination."

The SANITARY RECORD says:—

"Superior to other powders of this kind."

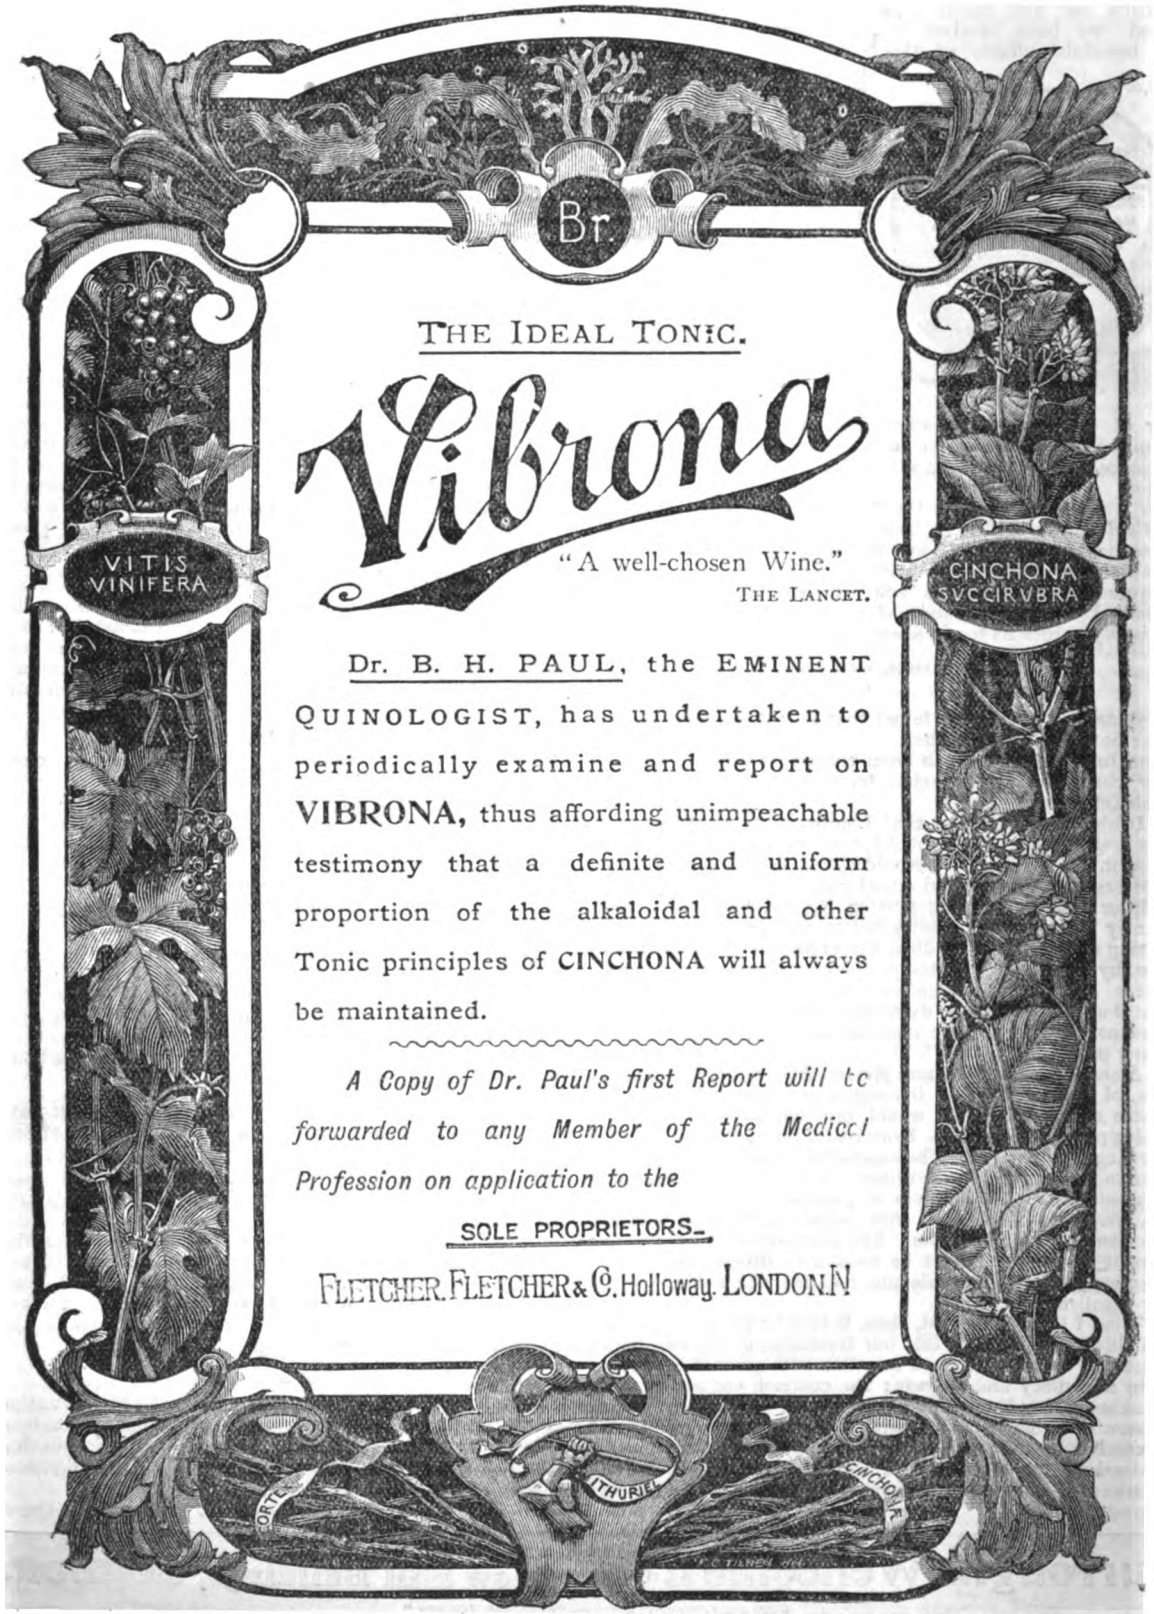
A CORRESPONDENT, PRACTISING IN THE NORTH OF SCOTLAND, writes:—

"Within the last fortnight I came across a very severe case of eczema infantiles of the face, head, and other parts of the body. After trying some other remedies with doubtful effect, I bethought me of your Emol-Keleet, and gave some to the mother to use as directed. Its effect has been most gratifying to myself, and highly beneficial to the little sufferer, who is only seven months old."

AS FURTHER EVIDENCE OF THE UTILITY OF THE NEW PRODUCT, WE QUOTE THE FOLLOWING EXTRACT FROM A LETTER FROM AN EMINENT SURGEON:—

"I beg to state that since Aug. 30th, 1894, I used 'Emol Keleet' to a big and sluggish ulcer on a man's arm with better results than I had previously obtained from dressings. The ulcer closed up rapidly after commencing with 'Emol Keleet,' and it is now practically healed up. It held on a stubborn course for about four months, but, being due to blood-poisoning, I was not surprised; yet I firmly believe that if I had had the 'Emol-Keleet' earlier the ulcer would not have been so sluggish in healing."

AN INFIRMARY HOUSE SURGEON writes:—



"I have used 'Emol-Keleet' in a case of acute irritation and rawing of the skin from bilious secretions through a fistulous opening. Everything I could think of having failed I tried the powder, and it has acted splendidly, and has been very comforting to my patient."

The Baillie Lectures
ON
DROPSY.

Delivered at St. George's Hospital on June 19th and 26th and July 3rd, 1895,

BY W. HOWSHIP DICKINSON, M.D., F.R.C.P. LOND.,

HON. FELLOW OF CAIUS COLLEGE, CAMBRIDGE; CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE II.

Delivered on June 26th, 1895.

GENTLEMEN,—I propose to devote the two remaining lectures to the subject of dropsy, one which has its points of contact with the cardio-vascular question which occupied the first, and is of paramount interest to the physician as connected with many diseases and productive of many results. Dropsy, like many other morbid conditions, is merely an exaggeration of a state of health. There is a continual outpour of lymph from the capillaries, some of which is employed in nutrition, some absorbed by the lymphatics, and some by the veins. In health this fluid is carried off as fast as exuded so that there is no accumulation; if there be accumulation it constitutes dropsy. This may be produced either by an increase of outpour or a diminution of removal; and the diminution of removal may be hypothetically attributed either to the veins or the lymphatics. I shall endeavour to show how these processes or failures to proceed are brought about, and what bearing they have upon the symptom in question; and my point of view, I need not say, will be mainly clinical or from the standpoint of human pathology. First let me exclude inflammatory effusions from present consideration. Looking at dropsy products for information as to dropsy processes we are at once confronted with the fact that this effused liquid in a given situation is much the same whatever the disease which has given rise to it. It varies much with place; little with origin. I have dwelt upon this fact in a paper to which I may venture to appeal[1] for particulars. I will here content myself with reproducing the average results of a series of estimations which I have made from time to time as opportunity offered; there to be found in detail.

sometimes the pleural more than the peritoneal, sometimes the reverse. When due to heart disease, the effusions contain more albumen than when due to kidney disease. The peritoneal effusions of cirrhosis of the liver occupy an intermediate place in this respect. The smaller amount of albumen under kidney disease corresponds with the reduction of this substance in the blood in the same condition. With this allowance it may be said that the effusions in each place are much the same in every disease, a resemblance which suggests that there must be considerable resemblance also in the processes by which they are produced. The saline ingredients are probably the simple results of dialysis. The albumen as a colloid body cannot traverse by this means but obtains its passage by pressure, by secretion, or by both together. Looking briefly at some of the physical facts which bear upon the subject we first have osmosis or dialysis, in virtue of which crystalloids traverse membranes until the liquid on one side is as fully charged as that on the other. This does not explain dropsy but only accounts for the saline constituents of dropsy fluids. Colloids such as albumen do not so traverse if the pressure on both sides is equal, but if it be unequal, then albuminous fluid-serum, for example, passes with facility in the direction of least resistance. In experimenting with membranes and liquids with regard to the processes of dropsy, so far as they could be imitated outside the body, the agent which presents itself as efficient beyond all others in moving albuminous fluids, and indeed fluids of all sorts, through membranes is pressure. If serum be placed at different levels on either side of a membrane the liquid will quickly traverse in the direction of least pressure until an equilibrium is attained. The action of osmosis is insignificant. It is true that if we put on either side of the septum liquids having opposite or very different chemical properties, acid and alkali, alcohol and water, &c., we may get osmosis which will be abundant against gravity and pressure; but such large transfer has always been between liquids which have been contrasted beyond what is possible in the process of serous effusion. As an agent in dropsy osmosis may be put aside as taking little part in it. Intravascular pressure and some process outside the vessel akin to secretion, the one physical, the other vital, remain for question. The action of the physical agent is certain and obvious, that of the vital is hypothetical. The overruling influence of pressure in the transmission of fluids, whether along vessels or through membranes, needs no insistence; it is the chief agent in the circulation and in all that depends upon it—exudation, nutrition, and cell function.

For the purposes of practical medicine dropsy may be described as having two modes of origin—(1) increased

Average Constituents of Dropsy Liquids in 100 Parts (from observations by Dr. W. H. Dickinson).

Disease.	Pericardium.			Pleura.			Peritoneum.			Cellular tissue.		
	Specific gravity.	Albumen.	Mineral salts.	Specific gravity.	Albumen.	Mineral salts.	Specific gravity.	Albumen.	Mineral salts.	Specific gravity.	Albumen.	Mineral salts.

Cirrhosis of liver	—	—	—	—	—	—	1012·8	2·25	0·842	1009·5	1·39	0·804

* These estimations relate only to a single case.

The first fact to be noticed is the uniformity of the mineral salts. In every place and from every cause these salts present nearly the same proportions—almost exactly that in which they exist in the blood. This looks as if they owed their exit to some unvarying physical law like osmosis or dialysis, and to this we may fairly attribute the presence of these crystalloids in the effusions of dropsy. No such uniformity holds with the albumen, which varies much—more with the location than the disease. Œdema fluid contains only traces, whatever the cause may be; when cardiac, the albumen is greater by about one-half than when renal. Pleural and peritoneal effusions are always highly albuminous,

blood-pressure and (2) alterations in the blood itself, which two conditions often occur together. I am not about to dwell on the physiological or experimental aspect of dropsy as it relates to the lower animals so much as upon the clinical and human, but a word or two as to the results of experiments on animals may be introduced. The simple observation was made over two hundred years ago by Lower that ligature of the vena cava was followed by dropsy of the parts below. Subsequent experimenters failing to get œdema as the result of simple ligature found it to be produced when in addition to the ligature upon the vein the nerves of the limb were cut. That section of the vaso-motor nerves should enhance the effect of venous obstruction is only what would be expected. Venous impediment fills the capillaries much; vaso-motor paralysis,

[1] On Renal Dropsy. Transactions of the Royal Medical and Chirurgical Society for 1892, vol. lxxv.

Digitized by Google

by increasing the arterial supply, must fill them more. Again, it has been found that ligature of the lymphatics promotes the process of dropsy. This, again, is only what might have been presumed. Dropsy fluid is the excess of capillary exudation over absorption; the less removed the more must remain. Practically, however, lymphatic obstruction may be put aside as a cause of dropsy in the human subject. Obstruction of the lymphatics causes, as we know, elephantiasis and chyluria, but not dropsy. Dr. Lazarus-Barlow, of this hospital and Cambridge, has recently made some careful experiments on this subject, which require to be considered in conjunction with those referred to. He showed that œdema did not come on *immediately* upon ligature of a vein—that is, not within an hour. I presume it did so ultimately. This negative result has little bearing on human pathology, where we have to do with long-continued conditions. Dr. Lazarus-Barlow is opposed to the mechanical theory of dropsy, and attributes much to anæmia of the tissues and the accumulation in them of waste products. Those who wish to follow Dr. Lazarus-Barlow's experiments must read his paper. As concerns human pathology it is not possible to doubt that increase of intra-vascular pressure, whatever be the intermediaries, has a paramount concern in the production of dropsy, while the establishment of toxic conditions—poisoning of the blood and tissues by excrementitious matters—has also a bearing on the morbid process.

Coming now to human pathology, the bearing of pressure upon dropsy is well illustrated in œdema. Everybody knows that a limb may swell from no other cause than a tight bandage, or ankles become œdematous only from long standing. Œdema of the legs, whether cardiac or renal, will continually go away under the influence of the horizontal posture; the fluid does not merely shift its position, but may be altogether removed. I have seen this over and over again, and regard the fact as of the first importance in the treatment of œdema of every kind. With mechanical advantage the veins empty themselves and allow the capillaries to do the same, while exudation lessens as intravascular pressure diminishes. The effects of venous obstruction, or, in other words, of increased pressure within the tributary vessels, are illustrated with sufficient simplicity by many forms of local dropsy. The consequences of the closure or narrowing of veins, whether by internal clot or external compression, are so well known that I need not dwell upon them. Œdema limited to the regions drained respectively by the vena cava, an innominate, or a femoral is so constant a result of venous obstruction that we have no hesitation in diagnosing a mechanical impediment as soon as we discern the local œdema.

One of the most instructive, and to the physician one of the most interesting, of the local dropsies is hepatic ascites. Cirrhosis puts a ligature, so to speak, or rather a multitude of ligatures, on the portal vein in its ultimate distribution in the liver, and all the portal tributaries become overfull and overtight until their contents in whole or part are forced through their walls by accumulating pressure and discharge blood or serum according to their position on a mucous or a serous surface. Thus we get hæmorrhage from the stomach and bowels in one case and in another ascites; seldom both together. The vessels are relieved either by bleeding or dropsical effusion; seldom by both in the same person. I have known the abdomen to break open through the umbilicus as a result of this form of ascites; and it is well known that gastric hæmorrhage as a result of portal obstruction may be fatal on the spot. In connexion with the mechanical and unyielding origin of hepatic ascites I may say a word as to the treatment of this the most obstinate of all the forms of dropsy. Ascites of other kinds—cardiac, renal, and tuberculous—will continually yield to treatment or time, but this seldom does so. It is remarkable how frequently ascites of tuberculous origin will take itself off notwithstanding the permanent nature of the cause to which it is due. I have got to regard a child with a tuberculous and watery abdomen with something of affection, as one which is likely to do me credit; so also may we obtain credit, though perhaps sometimes nature deserves it, with the ascites of heart disease and of kidney disease; but hepatic ascites usually holds medicine in scorn. Theoretically, purging should do good by relieving the portal pressure, but, as Sir Thomas Watson said, it must be hard purging, and even that is not productive of commensurate results. Practically we can do little. Reputed diuretics are in my experience useless. When extreme distension is reached, so far as to embarrass the respiration—and this is the rule I lay down for myself—we must tap, and the later the better, for tapping is generally the beginning of the end. The operation has to be repeated with lessening intervals until the patient succumbs. This is the rule; I will not say that there are no exceptions, but they are certainly few. I have often been struck with the enormous amount of fluid of this origin which may be carried about with the maintenance of fair general health and mobility.

I shall touch presently upon the general relation of drinking to dropsy, but in the meanwhile I will say with regard to hepatic ascites that in despair of other means I have tried dehydration by diet. Diminishing the volume of the blood must lessen the ascitic tendency by reducing the amount which has to make its way through the portal vein; we cannot widen the street, but we may diminish the traffic, and so do away with the block. In another point of view the blood has the property of maintaining or restoring its composition at the expense of anything else available; hence if we dehydrate the blood that fluid may recoup itself at the expense of serous effusion—for the effusion after all is chiefly water. A boy aged seven came under my care in this hospital on April 24th, 1886, with extreme ascites, a greatly enlarged liver, and a history of drink. According to his own account he "had beer to drink on week days and gin on Sundays, and liked the gin best." The distension was extreme, and the distress and dyspnœa such that early relief was imperative. He was tapped with Southey's tube six days after admission, again the next day, and, the fluid rapidly recollecting, for a third time four days later. To sum up, he was tapped ten times between April 28th and June 21st, and a total of fifty imperial pints removed; on an average he was tapped every five days and a half to the amount of five pints, pretty well considering that his weight was only 2 st. 9 lb. Knowing that this process could not go on much longer, I determined to try what could be done by dehydration—in other words, by dry diet. He was tapped last on June 21st; by the 29th the fluid had again reaccumulated to a large extent. I now put him on the following regimen:—Half the fish of fish diet, half a light pudding, two eggs, ten ounces of milk, an ounce and a half of brandy, and some acid drops. No medicine or a drop of liquid of any kind beyond what has been mentioned. On July 3rd the milk was further reduced to six ounces, so that the total daily liquid, including the brandy, was seven ounces and a half. His urine during this time (from July 3rd to July 26th) averaged fourteen ounces a day—nearly twice as much as the liquid he drank. Of course, there was a certain amount of water contained in his solid food which helped to make up the difference. Beyond this he lived upon himself and, so to speak, drank the contents of his own peritoneum. The beneficial effects were striking and immediate, the evil effects none. There was no inconvenient thirst, no dryness of the tongue. The dropsy rapidly diminished, so that by July 21st no evidence of abdominal fluid could be obtained. His appetite was good and he was practically cured of his dropsy, though the liver still remained of large size. He went to Wimbledon Convalescent Hospital on Aug. 18th, from which institution he was shortly dismissed for misbehaviour. He was readmitted into St. George's Hospital on Sept. 22nd of the same year, chiefly in order that he might be examined. There was then no fluid. He had no return of his dropsy. When at home he was allowed but little liquid. To use his father's words, "He was cautious and 'cute enough not to drink much." The last scene opened on Dec. 27th, 1888, when he was readmitted with acute head symptoms, which proved fatal on Jan. 2nd, and were found to have been connected with an abscess of the brain probably due to bone, though the origin could not be satisfactorily traced. This obviously had nothing to do with his former disorder. The peritoneum was universally adherent, the liver contracted and highly cirrhotic, weighing twenty ounces. What had occurred in the process of cure was clear: the peritoneum was emptied and kept empty by dehydration; the two surfaces, no doubt, more or less irritated by what they had gone through, or rather by what had gone through them, quietly stuck together and obliterated the cavity. I have tried this method in other cases of the same disease, but not with equally satisfactory results. The patients were all adults and proved less amenable than the child. I have generally been able by this means to reduce the circumference of the abdomen by two or three inches, but never succeeded in emptying it, and came to the conclusion that the relief was not so great as the inconvenience.

To save repetition I will here venture upon a digression and say something about water-drinking in relation to dropsy in general. *Crescit indulgens sibi dirus hydrops* expresses the belief of antiquity, and that this has come down to modern times is known to the readers of Boswell.[2] Dr. Johnson described the wine in Scotland before the union as "weak stuff, the refuse of France, which would not make you drunk." Whereupon, says Boswell, standing up for the honour of his country, "I assure you, Sir, there was a great deal of drunkenness." "No, Sir," retorts Johnson, "there were people who died of dropsies which they contracted in trying to get drunk." The immortal Pecksniff[3] is at one with the great Lexicographer in attributing dropsy to aqueous drinks. "If we indulge in harmless fluids we get the dropsy; if in exciting liquids we get drunk. What a soothing reflection is that!" The fact is that water does not cause dropsy, but alcohol does, which should be "a soothing reflection" to those worthies the tee-totalers. *A priori*, it might have been expected that much water would cause dropsy by increasing intravascular pressure and diluting the blood; but practically so long as the natural exits are free the excess of water will make its way out by them and not by transudation into the tissues. Water is diuretic, diaphoretic, and purgative, and will not accumulate so long as it can escape. Water may even be a cure for dropsy instead of a cause of it. In acute renal dropsy dependent on tubal nephritis water may be the best diuretic we can employ. It increases the urine, washes out the tubes, carries off the accumulated excreta and relieves the dropsy, together with the other symptoms. I have given a pint of distilled water every four hours with the beneficial results I have mentioned. But if the kidneys are so far gone that they cannot respond the dropsy will be increased instead of diminished; this I have also seen. The contrary plan, the cutting off of water, is one which should never be employed in the presence of renal disease; the dropsy may possibly be lessened, but the tendency to uræmia will be increased. In some forms of chronic renal disease the urine is thin, poor, and copious, and the patient habitually thirsty. So long as he is allowed to drink according to his needs the urine may remain superabundant and make up in quantity what it wants in quality. If on any false theory the drink is restricted what we may expect is uræmia. I will bring this digression to an end with the conclusion that there is a little truth and much error in the old dictum. Water increases dropsy when the kidneys are incapacitated, not otherwise. It is actually a remedy for dropsy when this is caused by nephritis, mainly tubal, and not too obstinate. The great source, at least of abdominal dropsy, is not water, but alcohol.

ON FUNCTIONAL HEART MURMURS: THE MIMICRY OF ORGANIC DISEASE.[1]

BY DAVID DRUMMOND, M.D., D.C.L.,
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE; LECTURER ON PATHOLOGY, DURHAM UNIVERSITY.
